Conventionalism

How is it known that every number has a successor, that straight lines can intersect each other no more than once, that causes precede their events, and that the electron either went through the slit or it did not? In cases like these it is not easy to find observable evidence, and it is implausible to postulate special modes of intuitive access to the phenomena in question. Yet such theses are relied on in scientific discourse and can hardly be dismissed as meaningless metaphysical excess. In response to this problem the positivists and empiricists (notably Poincaré, Hilbert, Carnap, Reichenbach and Ayer) developed a strategy known as conventionalism. The idea was that certain statements, including fundamental principles of logic, arithmetic and geometry, are asserted as a matter of conventional stipulation, being no more than definitions of some of their constituent terms; consequently they must be true, our commitment to them cannot but be justified, and the facts in virtue of which they are true are simply the facts of our having made those particular decisions about the use of words. This doctrine was a compelling and powerful weapon in the positivist-empiricist arsenal, evolving throughout the 1920s, 1930s and 1940s. But it fell into disfavour under a barrage of serious challenges due mainly to Quine. How are 'conventions' to be identified as such? How could they possibly provide words with meanings, or have the epistemological import that is claimed for them? How could arbitrary, contingent decisions about the use of words result in the existence of necessary facts? In the absence of satisfactory replies to these objections few philosophers these days believe that conventionalism can settle the semantic, epistemological and metaphysical questions that it was intended to answer. However, certain aspects of the view remain defensible and interesting.

1 The scope and nature of conventionalism

Conventionalism is the strategy of supposing that certain theses are implicit definitions - hence mere choices of language - and hoping thereby to explain how their adoption can be justified and to specify that in which their truth consists. It has been applied to the principles of deductive inference, to the claims of mathematics, and to 'bridge laws' specifying the observational consequences of theoretical hypotheses - all domains in which methods of *empirical* verification might seem to be inappropriate. For example, it was said that the axioms and rules of classical deductive logic are nothing more than implicit definitions of the logical constants, 'and', 'not', 'every', and so on; and this was supposed to show both how our reasoning could be justified and to articulate what it is to be a logical truth. Another famous application was to questions about the structure of space. It was maintained by H. Poincaré (1905) that geometrical facts are matters of convention: thus if we decide to use Euclidean geometry, we thereby implicitly define the terms 'point' and 'line' in such a way that the theorems of Euclidean geometry are true. We are therefore justified in employing any geometry we please; for there are no facts about the structure of space that could make some choices correct and others incorrect. A variant form of conventionalism about space and time was urged by Reichenbach (1968). In his view what stand in need of stipulation are certain correlations between spatiotemporal and physical properties (for example, that light travels in straight lines, and that pendulum swings consume equal periods of time). The idea here was that only once such 'coordinative definitions' had been decided upon would it become possible to investigate empirically the structure of space and time; alternate conventions will yield alternate answers, and so there are no facts of the matter as to which answers are correct (see Reichenbach, H. §4; Relativity theory, philosophical significance of §3).

Thus, to whatever domain it was applied, conventionalism in its standard form consisted in the following four elements: one, that some specified, determinate body of sentences (or rules) is accepted as a matter of conventional stipulation; two, that these commitments implicitly define certain constituent terms; three, that the propositions which the sentences express are known a priori; and four that those propositions are true - and the corresponding facts exist - in virtue of our conventional stipulations. In the following sections we shall consider objections to each of these components of the doctrine.

2 The definition of 'convention'

In the ordinary sense of the word a *convention* is an explicit agreement to act in some specified way. But, in that sense, no convention has ever been adopted to go around saying ' $1 + 1 = 2$'; and similarly for the other cases in which conventionalism was deployed. Thus emerges one of the fundamental difficulties faced by this philosophy: that of explaining how to demarcate 'conventions' or 'stipulations' (in the intended technical sense) from other

utterances we are inclined to make. R. Carnap (1950), perhaps the most sophisticated practitioner of the strategy, equated ‘linguistic conventions’ with the analytic (framework) sentences that determine what our words mean and which language we are using. These were in turn identified as the sentences which we decide to accept on the basis of pragmatic rather than epistemological considerations, and it was concluded that the propositions expressed by those sentences are known a priori. However, Quine’s (1935, 1951, 1954) influential critique of conventionalism made a strong case that although these conceptions of ‘convention’, ‘meaning’, ‘language’, ‘pragmatic reason’, ‘analytic’ and ‘a priori’ may well be linked in the way that Carnap supposed, they are all equally obscure and equally in need of clarification, and that it remains to find a way of breaking out of the circle of inter-definable ideas in order to characterize any one of them objectively (see Quine, W.V. §8).

3 The semantic component of conventionalism

The legitimacy of *deciding* that a certain set of sentences (or rules of inference) is to qualify as correct rested on two assumptions: first, that we are at liberty to decide which language to speak, for example, what our words are to mean; and, second, that in stipulating that a sentence be true we are merely fixing the meaning of one or more of its constituent terms. But the second of these assumptions has received considerable criticism, notably in the writings of Frege (1903, 1906), Prior (1960), Belnap (1962) and Dummett (1977). The thesis in question tends to be construed as follows: that in deciding to regard ‘Čnum;F’ as true, one is implicitly deciding to give ‘F’ whatever meaning it would need to have in order that ‘Čnum;F’ be true, given the already established meaning of the rest of the sentence, ‘Čnum;_’. But this thesis is far from obviously correct. In the first place, how can we be sure that there exists *any* meaning which could be assigned to ‘F’ and which would render ‘Čnum;F’ true? Second, how can we be sure that there is only *one* such meaning? Third, even if there is such a meaning, what reason is there to suppose that this is the meaning that ‘F’ acquires? And fourth, even if it is, how does our treating ‘Čnum;F’ as true *bring it about* that ‘F’ acquires that meaning: what account of the nature of meaning could explain how this happens? The difficulty of answering these questions casts doubt on the possibility of implicit definition.

4 The epistemological component of conventionalism

The main point of the doctrine was to show how our views about logic, arithmetic, spatiotemporal structure, and theory-observation relations could be rational, despite the absence of intuitive or empirical access to those domains. The idea was that our claims are justified a priori - independently of intuition or experience - because they merely fix the meanings of terms, which are commitments that are not subject to a posteriori constraint. Now we have just seen how the feasibility of implicit definition may well be questioned. But there is an additional problem concerning the alleged non-empirical character of such conventions. For even if it is conceded that by regarding a sentence as true one can fix the meaning of one of its constituents, there can remain a doubt as to whether the truth of that sentence is known a priori. The grounds for this doubt derive from Quine’s web-of-belief model of theoretical development, according to which our total theory formulation evolves under the constraints of empirical adequacy, global simplicity and conservativism (see Quine, W.V. §3). For if this model is correct then every element in the web earns its keep empirically by contributing towards the overall system that ‘best’ satisfies these three desiderata, and so everything we believe is a posteriori. This is not to deny that our commitment to ‘Čnum;F’ might implicitly define a constituent term ‘F’. The point rather is that given Quine’s model not even such meaning-constituting principles would be known a priori (see A priori).

5 The metaphysical component of conventionalism

On the metaphysical front, the standard conventionalist stance is blatantly antirealist; for insofar as a certain fact is merely a matter of convention, it evidently does not exist independently of us and our practices (see Scientific realism and antirealism). And this metaphysical thesis has provided a glaring target for criticism. For although it is no doubt a fact about us that we decide to commit ourselves to the truth of, for example, ‘ $1+1=2$’, this fact regarding our commitment is not plausibly identifiable with the arithmetical fact that $1+1=2$. The former fact concerns words, the latter numbers. Moreover, the former is contingent - there are possible worlds in which we decide to adopt different conventions - whereas the latter is necessarily the case - there is no possibility that $1+1=3$. Thus the conventionalist’s metaphysical thesis, implying as it does that if we had spoken a different language then perhaps $1+1$ would have been equal to 3, is extremely unattractive and has helped bring the entire

doctrine into disrepute.

6 Prospects for the defence of conventionalism

The above criticisms need not be considered decisive. In each case replies might be devised, involving modifications of the standard four-pronged doctrine. Thus, in response to the challenge to demarcate the class of conventional stipulations, one might abandon the intuitive concept of ‘convention’, with the presumption that it is evident when such things occur, and look to empirical linguistics for a characterization of which regularities in the use of a term (including assertions containing it) are explanatorily basic and hence implicitly define it. As for the difficulties with implicit definition, one might hope to pre-empt them by altering the assumption that, in regarding ‘Čnum;F’ as true, one is giving ‘F’ the meaning it would need to have for ‘Čnum;F’ to be true. Instead, again invoking a use-conception of meaning, one might suppose that, in regarding ‘Čnum;F’ as true, one is giving ‘F’ the meaning that is constituted by that rule of use (Horwich 1997). In that case the four above-mentioned difficulties could not arise. For the existence and uniqueness of a meaning is ensured by the existence of the regularity, and the explanation of how the convention provides meaning would be trivial.

Turning to the epistemological objection, one might resist the thesis that *everything* is a priori, which seemed to follow from the web-of-belief model. For there can surely be different formulations of the same theory - notational variants of each other. Therefore the decision to adopt one rather than another way of expressing one’s beliefs is a convention that is not subject to a posteriori revision. Thus the acceptance of a theory, Tabc, formulated using new terms ‘a’, ‘b’ and ‘c’, may be regarded as the product of two commitments: one being the substantive existential belief that there are unique theoretical properties, x, y and z, satisfying Txyz; and the other being the linguistic decision to call those properties ‘a’, ‘b’ and ‘c’. This conditional thesis, $(\exists!\mathrm{xyz})(\mathrm{Txyz}) \rightarrow \mathrm{Tabc}$, would not be held a priori (Lewis 1970; Horwich 1986).

Finally, the metaphysical critique of conventionalism could be accepted and accommodated by jettisoning the antirealist component of the standard doctrine. It would still be supposed that certain sentences (‘conventions’) implicitly define certain of their constituents; but it would no longer be maintained that the facts expressed by those sentences are reducible to facts about our practices, hence matters of convention.

Thus one might respond to the variety of objections to conventionalism. But this can hardly qualify as a vindication of the doctrine. For the revised defensible position which the objections have compelled solves none of the epistemological or metaphysical problems for which conventionalism was invented. Moreover, there is now reason to suspect that there were no real problems here in the first place. For Quine’s model suggests that logic, geometry, arithmetic and our theory-observation bridge principles have an epistemological and metaphysical status that is no different from the rest of what we believe. This still leaves open the possibility of implicit definition: the conventional a priori decision to use these words rather than those in the articulation of our beliefs, including those of logic, mathematics and science. But this is such a pale shadow of the original positivistic idea, it might be as well to reserve the term ‘conventionalism’ for that doctrine and consider it refuted.

Conway, Anne (*c*.1630-79)

Anne Conway (née Finch) was the most important of the few English women who engaged in philosophy in the seventeenth century. Her reputation derives from one work published after her death, Principia philosophiae antiquissimae et recentissimae (1690), which proposes a Neoplatonic system of metaphysics featuring a monistic concept of created substance. The work entails a critique of the dualism of both Descartes and Henry More, as well as of the materialism (as she saw it) of Hobbes and Spinoza. In her concept of the monad and her emphasis on the benevolence of God, Conway's system has some interesting affinities with that of Leibniz.

Anne Conway (née Finch) studied philosophy with the Cambridge Platonist, Henry More, who instructed her by letter since, as a woman, she was debarred from attending university (see Cambridge Platonism). She was introduced to philosophy through the study of Cartesianism in the modified - and therefore critical - version accepted by More. Later in life she encountered the physician and thinker, Francis Mercurius van Helmont, who brought her into contact with alchemical thought and the Jewish Kabbalah, and appears to have provided the catalyst for her turning away from the dualism of her Cartesian and Cambridge-Platonist background. Conway's *Principia philosophiae antiquissimae et recentissimae* (1690) is a Latin translation of a manuscript found among her effects after her death and published under the auspices of van Helmont in a collection entitled *Opuscula philosophica*. It was translated back into English and published as *The Principles of the Most Ancient and Modern Philosophy* in 1692. The original manuscript is lost and the printed version is probably incomplete.

Conway posits three orders of being: God, Christ or *Logos*, and 'Creature' or created substance. Where God is essentially unchanging ('a Spirit, Light, and Life, infinitely Wise, Good, Just, Mighty, Omniscient, Omnipresent, Omnipotent, Creator and Maker of all things visible and invisible', [1690] 1982: 149), creatures are characterized by mutability, with Christ as 'Middle Nature' linking God with creation. Created beings or species are modes of one single spiritual substance which comprises an infinite number of hierarchically arranged spiritual particles or monads. What is commonly taken to be matter is in fact less refined spirit - congealed spirit, as it were. All creatures are made up of a combination of both refined and congealed spirit. Created substance may increase in perfection, becoming more spiritual, or fall away from perfection, becoming more like matter. So also creatures themselves can move up or down the ontological scale, transmuting into higher or lower orders of creature: a grain of dust or sand 'through various and succedaneous Transmutations' may come to acquire the noblest attributes of substance, namely 'a capacity of all kind of Feeling, Sense, and Knowledge, Love, Joy, and Fruition, and all kind of Power and Virtue' ([1690] 1982: 225).

Conway developed her scheme in part as an answer to what she saw as the shortcomings of contemporary philosophy, the key error of which was, in her view, the mechanical concept of matter as inert, devoid of life and sense. As a result, mechanism was unable to account for action and life. Although she commends Descartes for his 'Mechanical Skill and Wisdom' she denies that understanding the laws of local motion can explain the vital operations of nature. Hobbes and Spinoza compound the problem by conceiving God in material terms and thereby confounding God with created things. While she accepts an instrumental role for local motion in the operations of nature, Conway conceives motion to entail change in general, defining it more broadly as a vital operation of the 'Strength, Power and Virtue', intrinsically present in substance as modes of substance and capable of extending their influence beyond that substance. Interaction between creatures is by a process analogous to emanation or radiation. Conway calls this 'virtual extension', that is 'a Motion or Action which a Creature hath… proceeding from the innermost parts' ([1690] 1982: 229) and reaching to other creatures through a proper spiritual medium. This spiritual principle of causality may be likened to a field of force, and provides the dynamics of perfectionism in Conway's ontology.

These modal transmutations of substance are also spiritual in the religious sense of that term, since the degeneration away from perfect spiritual substance which is entailed in the monads' becoming more like matter is also a falling away from the goodness of God. By the same token the purification of substance to become more spirit-like involves a return towards goodness and hence towards God. Conway's concept of substance thus underpins her soteriology: she denies the eternity of Hell, regarding the punishment of sin as corrective and ultimately salvific. Thus her overall ontological and spiritual scheme is in the end ameliorative, suffering being

explained as part of the process of moral and substantial purification by which ‘creature’ is restored to a more spiritual and therefore more divine state. Both in her concept of the monad and in her emphasis on God’s benevolence, her system has obvious affinities with that of Leibniz. Yet, although he expressed admiration for her, it is unlikely that she influenced him directly.

Copernicus, Nicolaus (1473-1543)

Copernicus argued that the earth is a planet revolving around the sun, as well as rotating on its own axis. His work marked the culmination of a tradition of mathematical astronomy stretching back beyond Ptolemy, to the Greeks and Babylonians. Though it was associated with methods and assumptions that had been familiar for centuries, it was also revolutionary because of its implications for the relations between humankind and the universe at large.

Around 1513 Copernicus composed the *Commentariolus*, a brief draft describing a new sun-centred system of astronomy. A few copies were circulated among astronomers, but it was not published until rediscovered in 1878. In the years that followed, he worked on a systematic programme of observation to allow accurate recomputation of the parameters needed for his heliocentric model. Despite his own conviction, however, Copernicus could not find a cogent argument for the counterintuitive claim that the earth *really* moves. It was only in 1540, when his disciple Georg Rheticus gave the first published account of the new system in his *Narratio prima*, that Copernicus was encouraged to complete and publish his long-planned work, the *De revolutionibus orbium coelestium* (1543). His friend, the Lutheran theologian Andreas Osiander, prefaced the work with an anonymous foreword asserting the hypotheses of the work were to be regarded as 'useful mathematical fictions only', thus misleading the first generation of readers into an underestimation of the revolutionary character of Copernicus' proposal. Only later did readers like Bruno and Kepler draw attention to the discrepancy between the message of the foreword and that of the main text.

In the opening lines of the *Commentariolus*, Copernicus describes what prompted him to undertake the immense labour of reconstructing and recomputing the entire system of astronomy. Ptolemy's equants, mathematical devices that allowed planets to move nonuniformly on the circumference of their circles, 'seemed neither sufficiently absolute nor sufficiently pleasing to the mind' (see Ptolemy). Copernicus discovered that placing the sun at the centre not only allowed him to save the phenomena, but also explained a variety of puzzling features of the planetary motions that Ptolemy had to leave as brute fact. In the heliocentric system, these turn out to be 'natural', necessitated by the fact that we are observing the sky, not from the centre, but from a moving vantage-point. Thus he could claim to have brought closer the 'mathematical' and the 'physical' approaches to astronomy that had so long been separated.

Copernicus attributed three motions to the earth. The first was a daily rotation on its own axis, the second a yearly revolution around the sun, the third, an annual motion in declination of the earth's axis (which later turned out to be unneeded). Attributing an annual motion to the earth allowed him to dispense with the larger planetary epicycles of Ptolemy, but the planets still required smaller epicycles in order to eliminate the equants. The first major achievement of Copernicus' system was that the relative distances of the planets could be determined, which the Ptolemaic model could not do. But other advantages were also plain. Making the earth the third planet explained the retrograde motions of the planets: the earth was lapping the outer planets and being lapped by the inner ones. The dimensions and periods of these apparent loops in the planetary paths could now be derived from the relative distances of the planets from the sun and their periods of revolution; in the Ptolemaic model, by contrast, the retrograde motions were an 'add-on', requiring arbitrary stipulation of epicycle parameters. Copernicus also noted why the outer planets are nearest and therefore brightest when in opposition (at the opposite side of the sky from the sun); in Ptolemy's scheme there is no particular reason why this should be the case. Finally, he could explain why Venus and Mercury are 'tied', as it were, to the sun, never appearing more than a certain maximum angular distance from it in the sky. Inner planets in a heliocentric system will *necessarily* appear 'tied' in this way; a puzzle for Ptolemy, because it linked the motions of these planets to the motion of the sun in a way that could be arbitrarily postulated but that defied explanation in his model.

Copernicus was a scientific realist (see Scientific realism and antirealism §1). He knew that the constructions of mathematical astronomers were traditionally regarded as no more than helpful fictions. He knew too that objections to the earth's motion would be urged by those who took a literalist approach to the wording of the Bible. Yet he was confident that he had shown that the earth *really* is in motion. Some recent historians have suggested that he was motivated by a Neoplatonic metaphysical belief in the cosmic primacy of the sun but there is

little real evidence for this. In book one of *De revolutionibus*, he makes the reasons for his realistic stand clear enough. He does not appeal to a superior accuracy of prediction nor to a reduction in the number of circles deployed. Rather, his system displays, he says, a 'harmony' that its rivals lack. And this is not an expression merely of an aesthetic preference. Superior explanatory power was for Copernicus something more than saving the phenomena: it convinced him that he had hit on the truth with regard to the earth's motions.

Cordemoy, Géraud de (1626-84)

Géraud de Cordemoy was, by profession, first a lawyer, then a tutor to the Dauphin (the future Louis XV). But he was also one of the more important Cartesian philosophers in seventeenth-century France. In Le discernement du corps et de l'ame, Cordemoy defended a strict dualist and mechanist philosophy. But his Cartesianism was unorthodox, since he introduced indivisible atoms into his natural philosophy and was one of the first to argue for occasionalism, the doctrine that God alone is a true causal agent. He also wrote an important work on the nature and origins of speech and language, Le discours physique de la parole.

Géraud de Cordemoy was born in Paris on 6 October 1626. A lawyer by profession, from 1657 onwards he regularly attended occasions at which Cartesian philosophical ideas were discussed, and his *Discours de l'action des corps* was incorporated into the 1664 edition of Descartes' *Le Monde*. His major philosophical work, *Le discernement du corps et de l'ame* (1666), was thoroughly Cartesian in inspiration, and was followed two years later by *Le Discours physique de la parole*. By this time his broad interests included politics, pedagogy and history. In 1673, through the influence of Bossuet, he was appointed *lecteur ordinaire* to the Dauphin and joined the vibrant intellectual circles at the court of Louis XIV. He also began research into the history of France, published posthumously as *Histoire de France*. In 1675 he was elected to the Académie Française, of which he later became director. He died on 15 October 1684.

Most of Cordemoy's philosophical work involved an unorthodox defence and development of Descartes' system. He worked hard, for example, at reconciling Descartes' cosmogony with the biblical account of creation. More important, however, are the modifications he introduced into Cartesian metaphysics and natural philosophy with respect to the nature of matter and causation.

Descartes' matter, or body, understood as pure extension, is by nature divisible *ad indefinitum*. (Descartes preferred to say that the extension of the world is indefinite but not infinite - only God is 'infinite.') Hence, there are no in-principle indivisible atoms. Moreover, whatever is extended is body, so that the universe is a plenum. Cordemoy accepted the Cartesian project of mechanistic physics according to which all natural phenomena are to be explained solely by means of the motion and rest of insensible particles of matter, each of which is characterized by geometrical features alone. But he held that the only consistent form of mechanism is atomism. In the *Discernement*, he distinguished matter from extended substance, or body. Substance is essentially indivisible. Bodily substances, then, are indivisible, impenetrable, extended atoms, each with an invariable figure. Matter, on the other hand, is constituted by collections of atomic bodies, between which there are empty spaces. Cordemoy argued that only an atomism can consistently account in a non-relative way for the individuality and integrity of bodies. Moreover, a material plenum would render motion problematic and rectilinear motion unnatural, contrary to Descartes' own physical laws.

The *Discernement* next turns to the nature of causal relations, both between bodies and between bodies and minds. Cordemoy is generally regarded (along with La Forge) as one of the originators of the modern doctrine of occasionalism (see Occasionalism; Malebranche §3). According to Cordemoy, bodies and minds are devoid of any real causal efficacy. One body cannot cause motion in itself or in another body, nor can it cause an event in the mind. And finite minds cannot cause mental events or move bodies. Only God, an infinite spirit, is a true causal agent. Cordemoy's argumentation proceeds in an a priori manner, starting from definitions and self-evident axioms. In the body-body case, one body cannot be the cause of motion in another body because motion is a state of a body, and states cannot be communicated from one substance to another. Moreover, no body causes motion in itself, since nothing has 'from itself' that which it can lose without ceasing to be what it is (one of Cordemoy's axioms), and a body can lose its motion without ceasing to be a body. It follows that the first mover of bodies is not a body, since such a first mover must have motion from itself. But there are only two sorts of substances: mind and body. Hence, the first mover of bodies must be a mind. Another axiom then states that an action can be continued only by the agent that initiated it. Thus, the mind that first moved bodies continues to move them. It is not *our* minds that move bodies. This is especially clear from the fact that bodies are usually moved independently of the volitions of any finite mind. This is true not just of inanimate bodies, but also of a great deal of the motion that takes place in the human body. What misleads us into attributing causal efficacy to minds and bodies is just

the constant regularity in the succession of states of things. But, Cordemoy says (as Hume would repeat), this regular succession is *all* that experience reveals to us (see Hume, D. §2). The true cause can only be an infinite, all-powerful mind - God - who, acting on the occasion of the antecedent event, brings about the appropriate effect. Taken in a broader context, Cordemoy's occasionalist project is to demonstrate the ultimate metaphysical foundations of the physics of Cartesian (but atomistic) bodies.

Cordemoy's other important philosophical contribution, while not present in the *Discernement* itself, is none the less intimately related to that work's mechanistic science of body and dualist anthropology. In *Le Discours physique de la parole*, Cordemoy's stated aim is an examination of the nature of speech and language. He studies both that part played in linguistic communication by the purely physical mechanisms of the body, and the semantic aspect contributed by the mind. He considers, as well, the process of learning language and certain questions (some ethical) related to eloquence.

Cordemoy's atomist and occasionalist modifications of Descartes' philosophy drew strong critical responses from other Cartesians (such as Dom Robert Desgabets). But he also impressed later thinkers, and Malebranche and Leibniz acknowledged his influence. More recently, the linguist Noam Chomsky identifies Cordemoy as an important contributor to the development of rationalist linguistics.

Corruption

Corruption denotes decay or perversion. The term implies that there is a natural or normal standard of functioning or conduct from which the corrupt state of affairs or action deviates. When we talk of a person becoming corrupt, we mean not just that they have broken a rule, but that the basic norms of ethical conduct no longer have any force for them. Corruption strikes at the root of a thing.

Political corruption involves the decay or perversion of political rule. Broadly, this occurs when a group or individual subverts a society's publicly endorsed practices for conciliating conflicts and pursuing the common good so as to gain illegitimate advantage for their interests in the political process. The precise specification of the nature and dynamics of corruption is inherently controversial. Classical accounts associate it with a collapse of civic virtue and the eventual destruction of the state. Modern theories focus more narrowly on the misuse of public office for private gain.

1 The historical tradition

The corruption of politics, as the decay of the capacity to pursue justice or the common good, was a central concern for political philosophers in antiquity, and it remained so for their republican successors until the end of the eighteenth century. Two paradigmatic accounts of this process are in books 8 and 9 of Plato's *Republic* (*c*.380-367 BC), which sketch a political sociology and social psychology of the decay of the ideal state into ever more debased and less fully human forms (see Plato); and book 3 of Thucydides' *History of the Peloponnesian War* (*c*.424-399 BC), in which the fall of Corcyrus is depicted in terms of the complete subversion of the political, social and moral order of the state (see Thucydides). For classical authors, corruption was only incidentally a case of bribery, malfeasance or profiteering; its core sense concerned the systematic subversion of those practices, institutions and beliefs that provided a society with a shared understanding and a shared set of purposes. Within this tradition we find accounts, of varying degrees of sociological subtlety, of the causal and material preconditions for political rule and for its decay. These centre around the destabilizing effects of economic inequality among citizens, the enervating effects of luxury, concern with the size of states and their populations, the role of military training and combat, the appropriate education for citizens, the threat of foreign contamination and the best constitutional structure for the state. Without attention to these factors, the capacity of citizens to live virtuously and to recognize the demands of the common good becomes corrupted and the state falls.

This part-normative, part-sociological project of theorizing about the material and cultural preconditions for the stability of states exerted a powerful influence on Western traditions of political thought from Polybius to Rousseau, with Machiavelli playing a central role. Through Aristotle, it had still wider influence on thinkers such as the fourteenth-century North African philosopher of history, Ibn Khaldun. In the UK it played a major part in the language of political opposition in the eighteenth century; thence it came to influence both American and French revolutionaries.

From the early modern period, however, there have been two counter-tendencies to this classical tradition. One denies that there is a common good for politics to pursue; instead, politics involves the pursuit of interests within institutional constraints, and claims about corruption are dismissed as emotive and as wholly motivated by factional or individual interests (as in Hobbes). The other narrows the focus, understanding corruption not as a systemic phenomenon but as a form of rule infraction or deviance by holders of public office. A precondition for this view is the separation of state and society, and the belief that civil society functions relatively autonomously from the state - corruption in government becomes seen as unrelated to the activities of social and economic life, and its solution is believed to lie with the construction of systems of scrutiny and mechanisms of accountability, rather than with the creation and sustaining of widespread citizen virtue.

2 Corruption in political science

Modern conceptions of corruption have tended to follow the more restricted ambitions of this view of corruption as individual rule infraction. Political scientists operate with two main, rival definitions: one centred around public office and one centred around public interest. The public office conception of corruption is exemplified by Nye: 'Corruption is behaviour which deviates from the formal duties of a public role because of private regarding

(personal, close family, private clique) pecuniary or status gains; or violates rules against the exercise of certain types of private regarding influence' (1967: 966).

For Nye, questions of the public interest are questions about the effects of corruption and should not be taken as definitional of the phenomenon. Others, however, have sought to define political corruption precisely in terms of a conception of the public interest. Carl Friedrich argues that we have corruption wherever an office-holder or functionary is induced by non-legitimated rewards to act in ways favouring the rewarder and thereby doing damage to the public and its interests (Heidenheimer *et al.* 1989: 10) (see Public interest §3).

Both public office and public interest definitions of corruption, however, must identify the norms by which we are to define the character and scope of public office or the public interest. Both definitions rely on such norms, but it is not obvious which norms we should accept. There may be little consensus within a society; official and popular mores may not coincide; and what people say about these norms may not coincide with how they behave. The law is equally deficient as a definitive source for norms, not least because laws can be the product of corrupt practices. Moreover, laws regulating political conduct rest on prior assumptions about the character of political office and the appropriate rules for its conduct - as such, legal norms are better understood as drawing on, rather than underpinning our understanding of public office.

These difficulties in identifying the norms of public office or the standard for the public interest ensure that the study of political corruption remains an unavoidably normative exercise. They also show that any theory of political corruption will require an understanding of the distinctive character of political activity and an account of the conditions in which this activity can resist subversion by competing values and activities in society.

A similar conclusion can be drawn by pressing the distinction between definitions of public-office and of public-interest. The conduct of public office, for the most part, is not (and cannot be) exhaustively prescribed by systems of rules. Most offices carry considerable discretion and flexibility, so as to allow occupants to respond to the contingencies of political life. But although the rules of office are open in this sense, the end or basic purpose of the office is unquestionably that it be guided by considerations of the public interest. Moreover, in identifying a rule violation as corrupt we are inevitably led to ask in whose interests the rule was broken. Depending on the answer to that question, we may judge an action as foolish, high-handed or misconceived, rather than corrupt.

3 The core of political corruption

These definitional problems, it should be emphasized, do not arise because the term corruption is unclear. On the contrary, its meaning is relatively uncontentious: it is rooted in the sense of a thing being changed from its naturally sound condition. The problem arises in applying this to politics since there is no general consensus on the 'naturally sound condition of politics'. Public office and public interest definitions focus on different aspects of the political; their disagreement is not over corruption, but over which criteria are appropriate to identify the naturally sound condition from which corrupt behaviour deviates.

It is at this point that the classical republican tradition, conceiving corruption in terms of the decay of the distinctive realm of human action which is politics, has renewed appeal (see Republicanism). Classical views identified a natural condition to politics, conceived in teleological terms, which provided the normative basis or standard which corrupt acts were seen as subverting or otherwise destroying. Modern political science is deeply uncomfortable with such normative commitments and yet, if we are to use the term coherently, such normative commitments are essential. They are essential because we cannot identify political corruption - and if we cannot identify it we cannot understand or explain it - without a commitment to some conception of the nature of politics which these acts subvert. Corruption is, then, the 'other' of politics; it is what must be overcome for properly political rule to be possible. The classical republican tradition had the conceptual and normative framework to recognize this relationship, but the scientism and historicism of the nineteenth and twentieth centuries, and the shift in concern from the conditions for attaining a commonality of purpose and interest within the polity to the problem of integrating the potentially insurgent masses into the bureaucratic politics of the modern nation state, served to displace the insights of this older paradigm. Indeed, political scientists have tended to concentrate their efforts on the understanding of corruption in deviant cases, such as in authoritarian states and command economies or as a transitional phenomenon in newly democratized regimes undergoing rapid economic development and social change, and have generally assumed that the modernization and liberalization of the state solves such

problems. Above all, in sharp contrast to the classical model, there has been very little attention paid to the correlation between the maintenance of an active civic culture and the incidence of corruption within the political domain. The result has been the development of models of politics which have, by eschewing questions of the distinctive nature or character of politics and underplaying the relevance of the mores and beliefs of civil society in the incidence of corruption, largely failed to provide an adequate understanding of what remains a widespread phenomenon in many modern states.

Cosmology

The term 'cosmology' has three main uses. At its most general, it designates a worldview, for example, the Mayan cosmology. In the early eighteenth century, shortly after the term made its first appearance, Christian Wolff used it to draw a distinction between physics, the empirical study of the material world, and cosmology, the branch of metaphysics dealing with material nature in its most general aspects. This usage remained popular into the twentieth century, especially among Kantian and neo-scholastic philosophers. But recent developments in science that allow the construction of plausible universe models have, effectively, pre-empted the use of the term in order to designate the science that deals with the origins and structure of the physical universe as a whole.

Cosmology may be said to have gone through three major phases, each associated with a single major figure - Aristotle, Newton and Einstein. The ancient Greeks were the first to attempt to give a reasoned account of the cosmos. Aristotle constructed a complex interlocking set of spheres centred on an immovable central earth to account for the motions of the heavenly bodies. Newton formulated a theory of gravitational force that required space and time to be both absolute and infinite. Though the laws of nature could, in principle, be specified, nothing could be said about the origins or overall structure of the cosmos. In 1915, Einstein proposed a general theory of relativity whose field-equations could be satisfied by numerous universe-models. Hubble's discovery of the galactic red shift in 1929 led Lemaître in 1931 to choose from among these alternatives an expanding-universe model, which, though challenged in the 1950s by a rival steady-state theory, became the 'standard' view after the cosmic microwave background radiation it had predicted was observed in 1964. The 'Big Bang' theory has since been modified in one important respect by the addition of an inflationary episode in the first fraction of a second of cosmic expansion. As a 'cosmic' theory, it continues to raise issues of special interest to philosophers.

1 Aristotle's cosmos

Cosmology and philosophy came into existence together in the Greek-speaking world of the sixth century BC when some daring minds sought a 'reasoned account' of the origins and nature of the universe. They assumed that the complex must originally have come from the simple, and thus sought clues in the world around them for the elements and processes responsible, resting their claims on argument rather than on the authority of a tradition. Plato was sharply critical of his predecessors' lack of attention to the traces of mind he saw everywhere in the world around; his *Timaeus* took the universe to be the work of a demiurge (artificer) who imposed partial order on a pre-existent and recalcitrant receptacle (see Plato §16). He acknowledged that his account fell short of knowledge proper. But it could still claim the status of a likely story.

Aristotle went much further, and the cosmology he constructed would substantially endure for two millennia. Beginning from the sophisticated geometrical combinations of circles whereby his contemporaries Eudoxus and Callippus had sought to 'save' the motions of the seven 'wandering stars', he proposed a set of fifty-five rotating concentric spheres, the poles of each carried by the sphere next outside it, and each given its own motion of rotation by an immanent mover, akin to a soul. The complex motion of each planet is the resultant of the motions of its own cluster of spheres, the innermost of which carries the planet. The physics of earth does not apply to these spheres, whose eternal circular motions are quite unlike the rectilinear natural motions found on earth. Nothing much further can be said about the nature of the spheres and the celestial bodies they carry except that they are incorruptible (see Aristotle §16).

The aim of Aristotle's cosmology was to give a plausible causal explanation of the planetary motions, and in this it succeeded. It was not of much practical use for the needs of working astronomers, and its concentric spheres could not explain the known regular variations in planetary brightness. The epicycles and eccentrics first introduced by Apollonius and Hipparchus and later welded by Ptolemy into an accurately predictive geometrical scheme were of much more use for practical ends, but could not compete with Aristotle's ingenious model in explanatory appeal. The fact that the two approaches could not be reconciled was troublesome, but medieval philosophers grew accustomed to arguing that the truth of things would be found in 'physics', that is, in causal explanation, even though 'mathematics' would perhaps be more effective for saving the phenomena.

2 Newton's infinites

Aristotle's cosmology fell as the Copernican heliocentric model (see Copernicus) gradually proved itself in the hands of Kepler and Galileo. In his *Astronomia nova* (1609), Kepler argued that a proper cosmology, one that could claim to give a true account of the motions and distances of the planets, would have to elucidate the causes of those motions and not merely save the phenomena. His own attempts to explain the motions in terms of forces acting at a distance were not successful. It was left to Newton to carry this programme through, utilizing a gravitational attraction that varied inversely as the square of the distance. Leibniz and the Cartesian physicists of the day were willing to concede that the new mechanics of Newton's *Principia* (1687) could save the phenomena, but they insisted that action at a distance could not be accounted an explanation, and hence that the *Principia* did not support a genuine cosmology (see Mechanics, classical §3; Newton, I.).

In order to support the reality of the forces he postulated, Newton introduced the idea of 'absolute' motion (changes in which would be the indication of forces acting) and its corollaries, absolute space and absolute time. Absolute space is Euclidean and thus boundless; it exists independently of any material contents, unlike an Aristotelian place. Absolute time 'flows equably without relation to anything external'; it is thus independent of actual physical change (unlike Aristotelian time) and it is without beginning or end. Not much purchase here for questions about the origin and extent of the material universe! A century later, indeed, Kant would argue that the proclivity of human reason to pose cosmological questions such as these, which necessarily (in his view) lead to antinomy, forces a radical critique of pure reason itself (see Kant, I. §8).

Newton made one significant cosmological claim. In Aristotle's universe, terrestrial and celestial bodies were altogether different in nature, so that a simple science of the two was impossible. Newton showed, however, that a single mechanics governed earth and planets, and in the boldly inductivist third rule of reasoning of the *Principia* postulated that qualities characterizing bodies at the local level should be deemed to characterize the universe generally. The inverse square law of gravitation could, on this basis, be portrayed as a cosmological law governing the attraction between any two particles in the universe. Kant was the first to see just how this might explain the origin of such stable cosmic structures as planetary systems or even the Milky Way. Questions about origin or structure at the level of the universe, however, still seemed fruitless.

3 The expanding universe

In 1915, Einstein formulated a general theory of relativity, employing non-Euclidean geometry to describe a unified spacetime in which the curvature of spacetime replaces gravitational force as a cause of motion (see Spacetime §3; Relativity theory, philosophical significance of §§4-7). Universe models could now be constructed as solutions to the field equations of the new theory, though constraints were needed on the large number of possible solutions. A variety of 'natural assumptions' were introduced regarding large-scale cosmic structure, some of them given the status of 'cosmological principles'. Notable amongst these was Einstein's daring conjecture that matter should be distributed uniformly over space on the largest scale. When Einstein discovered that his equations tended to yield unstable models, he added a cosmological constant representing a repulsion that increased with distance, since he assumed that a plausible universe model ought to be static. Alexander Friedmann (1924) and Georges Lemaître (1927) proposed, instead, nonstatic solutions in which space itself could be expanding.

Hubble's discovery of the galactic red shift in 1929 was the next significant development. It indicated that the galaxies are moving away from us, and from one another, at speeds proportional to their distances. Lemaître (1931) realized how neatly this fitted the nonstatic models of general relativity and formulated the theory of the expanding universe, later called the 'Big Bang' theory. From the rate of expansion, one could calculate an upper limit on the length of time since the expansion began from a single enormously condensed volume. An answer to the ancient cosmological query about origins suddenly seemed to be within reach. But a disappointment was in store. Using Hubble's figure for the expansion constant, the limit-age came out as roughly two billion years, much shorter than the estimated age of the solar system or of the oldest stars.

This was one, though not the principal, motivation for the construction of an alternative 'steady-state' model by Bondi and Gold (1947). It rested on what they described as the 'perfect' cosmological principle, requiring a homogeneous distribution of matter in an infinite space and throughout an infinite time. To account for the Hubble expansion, they postulated the continuous creation of hydrogen throughout space at a rate too low to be detectable, sufficient to allow new galaxies to replace the old as the old move out of view. Baade (1952) showed that Hubble's

estimate for galactic distances was too low and that the ‘Big Bang’ age in consequence was a much safer ten to twenty billion years. And in the late 1950s, evidence began to mount that the relative abundance of galaxies of different types varied with distance, contrary to the ‘perfect’ principle.

But it was the discovery by Penzias and Wilson of the uniform cosmic microwave background radiation, reflecting a 3K black-body temperature distribution, that proved decisive (1965). Alpher and Herman had predicted long before (1948) that just such a relic of radiation should be expected from the original Big Bang. The effect of the discovery was not only to bring over most cosmologists to the Big Bang theory but also, to a significant extent, it validated cosmology itself as a respectable branch of science. Fresh data concerning the observed cosmic helium abundance (25 per cent by mass) also fitted the Big Bang account of helium formation in the first minutes of the cosmic expansion.

Still, some serious challenges remained. In the Big Bang model, the universe might be (geometrically) ‘open’, in which case it would be infinite and galaxies would continue to expand indefinitely, or it could be ‘closed’, finite, with the galaxies ultimately collapsing again inwards, or ‘flat’, poised between. The decisive factor is the average cosmic mass-density. Collins and Hawking (1973) showed that for a long-lived universe like ours to develop, one in which the background radiation is isotropic, the early universe would have had to be ‘flat’ to an almost unbelievably exact degree. Cosmologists had always assumed that no particular initial cosmic parameter setting would be needed, so this discovery was both unexpected and unwelcome. Collins and Hawking responded with what Carter (1974) dubbed the ‘anthropic principle’: the fact that we have observed the universe to be long-lived and isotropic is merely a consequence of our own existence. Were it not to be of that sort, we would not be here! To convert this ‘principle’ into an explanation, a further premise was necessary. Their choice was a many-universe hypothesis: if our universe is one among a large number of actual universes, we would naturally find ourselves in one that is suited for human existence. Other writers, most of them philosophers of religion, pointed out on the other hand that such ‘fine tuning’ would be what one would expect were the universe to be the work of a provident Creator (see God, arguments for the existence of §5). Here, then, were two unconventional sorts of anthropic *explanation*, each requiring a much broader context than usual to make it acceptable. (It seems doubtful that there is a nontrivial anthropic *principle*, strictly speaking.) The same two alternatives were also proposed in response to a rather different sort of fine tuning. Were the physical constants, notably the relative strengths of the four fundamental forces, to be even very slightly different, a long-lived galactic universe containing the heavy elements needed for complex life would not have developed.

Alan Guth (1981) took a more conventional approach to the ‘flatness’ problem. He proposed a modification of the Big Bang model that would automatically bring about the critical mass-density needed: a gigantic inflation within the first fraction of a second of the cosmic expansion. This would also eliminate several other troublesome anomalies in the original Big Bang theory; it would, for example, achieve the needed causal coordination across different spatial regions of the early universe. The inflationary hypothesis illustrates the extent to which quantum theory has entered into the cosmological debate. On the one hand, standard quantum ideas have permitted physicists to reconstruct the probable sequence of the early expansion, allowing the derivation of testable predictions concerning, for example, the relative cosmic abundance of the lighter elements. On the other, the enormous energies and densities of the very first moments of the (hypothetical) expansion have become a conceptual testing-ground for quantum field theory of a sort that the particle accelerators of earth could never provide.

Cosmology is, as it has always been, a testing-ground for philosophical ideas, lying at the limits of our notions of space, time and causality. Inductivist doubts as to whether a unique object such as the universe could ever become a legitimate object of knowledge have been to some extent quieted. A theory of the universe can be tested as theory normally is, by such criteria as coherence, predictive novelty and consilience. The vast expansion in our conceptual horizons that Big Bang theory and its inflationary addendum have brought about have led philosophers to be more wary than they were of the sort of appeal to intuition on which philosophies of nature in the past were often based. For the same reason, reliance on ‘cosmological principles’ as anything more than idealizations of a regulative sort has become increasingly suspect. Discussions of anthropic forms of explanation have forced scientists and philosophers alike to clarify what counts as ‘explaining’ and what resources can legitimately be drawn on in the process. The many-universe models, particularly those prompted by the inflationary hypothesis, have raised new questions about what should count as a distinct universe. It is less than a century since Einstein

opened the new era in cosmology. No doubt surprises as great as those already encountered still lie ahead.

Cosmology and cosmogony, Indian theories of

Theories of the origin of the universe have been told as stories, riddles and instruction in India since early times. The three prominent religious movements, Hinduism, Buddhism and Jainism each had their own myths and speculations.

In the Hindu tradition there was never one single theory. Among the divergent ideas we can distinguish: an early stage, which included themes such as there being nothing at the beginning, or the universe being created by mutual birth, or creation as the dismemberment of a sacrificial victim, or the gods arriving after the first moment of creation; and a later stage, in which Viṣṇu or Brahmā was regarded as the creator of the universe. Simultaneously, the old Sāōkhya idea of the self-creating universe, in which the original material stuff transforms itself into the different parts of the universe, coexisted with the idea of a god creating the universe.

The early Buddhist tradition neglected questions such as 'Does the universe exist?' The first mention of such topics occurred in the Pāli Canon, where they were condemned. A few centuries later, these cosmological ideas were taken up by Vasubandhu, who collected them and formulated them in a comprehensive way. Without a creator god, the universe is primarily a reflection of meditational experiences of the world, a Single Circular System. There are several other systems, such as the Thousand Universe System, the Immeasurable Universe System and the Pure Land.

The Jaina tradition had a very detailed theory of the spatial arrangement of the universe. This was essential for understanding where all the individual selves travel to after death, given their spiritual accomplishments (or lack of them). From earth they go to heavens or hells, the aim being eventually to reach the place of bliss and thus to gain final freedom.

1 Vedic period

Just as the earliest speculations in many cultures revolved around questions and theories of the origin of the universe and related topics, so in India the earliest available document of the culture, the *Ṛg Veda* (*c.*1200 BC), preserves such ideas. It predates any divergence of the ideological movements. The references are scattered. In the oldest parts, cycles 2-9, the topics centre around separating heaven from earth. The creation of the universe is likened to the building of a house, and measuring is one of the main activities. The doors of the house face east and let in the morning light. Other artistic activities, such as weaving or forging, are used to describe the creation of the universe. But interpretations of the myths and speculations on the origin of the universe can be found only later, in the youngest parts of the *Ṛg Veda*, specifically the tenth cycle.

The tenth cycle contains a number of cosmological hymns. Several themes are discernible: in one hymn there is nothing at the beginning, in another there is mutual birth, another describes the dismemberment of a sacrificial victim, yet another the arrival of gods after the first moments of creation. Early cosmological questions such as 'Where did anything come from?' receive some intriguing treatment; hymn 10.129 says that 'At the beginning there was neither existence nor nonexistence'. The questions were often answered in the form of riddles.

Similarly, the Aditi hymn (*Ṛg Veda* 10.72) is ambiguous. First, Reality or Being arises from Nothing. After this, the skies come into being, born from vast spaces. The earth is born of the vast spaces. Often in the *Ṛg Veda* the sky and the earth are considered to be the parents of the various gods. Then Dakṣa is born of Aditi, the mother goddess. In the same hymn, Aditi is the daughter of Dakṣa. It is something like a mutual birth or an incestuous birth. The very same process of birth is found in the well-known 'Puruṣasūkta' (*Ṛg Veda* 10.90.), where Virāj (who is female) is born of Puruṣa, but in turn Puruṣa is born of Virāj. After the mutual birth in the Aditi hymn the gods come into existence and Aditi gives birth to seven sons, whom she takes to the gods. She also gives birth to an eighth son, whom she sets aside to be the human who procreates and dies.

The hymn of dismemberment of the sacrificial victim is called the 'Puruṣasūkta'. It describes the sacrifice of the Primeval Man, through which the world becomes filled with animals as well as all things and populated with people, who are grouped into four categories. Different parts of the Primeval Man are the sources of the social hierarchy and division of labour in Hindu society. Thus from the head of the Man come the priests, from his arms spring the warriors, from his thighs come the farmers and merchants, and from his feet emerge those who provide

services for the other groups. The dismemberment depicts the different strata of society while justifying class divisions that survive to the present day.

2 Upaniṣads and classical Hinduism

The main background for the variety of often unrelated and even contradictory speculations in Indian cosmology was provided at the time of the late Veda, especially during the time of the *Atharvaveda*, the Brāhmaṇas and the Upaniṣads (1000-600 BC).

The Upaniṣads do not form a uniform ideology, but rather represent a collection of speculations on the nature of things. Here we find, for example, a refutation of the early statement about the universe as born from nothing. In Chāndogya Upaniṣad 6, a father instructs his son, telling him that at the beginning there was only one being and from it all was born (see Monism, Indian §4).

In Chāndogya Upaniṣad 6 and other parts of the early Upaniṣads there is a convention of listing. Frequently we find lists of three items: fire, water, solid matter (called food), each of which in turn becomes threefold. The first sets of ontological categories were presented as lists, and this constituted the scientific method of the early period. The number four often plays an important role in lists of the basic elements: heat, water, the solid matter (called 'food') and the wind. Some thinkers added a fifth, space (*ākāśa*). Before the differentiation of separate religious and cultural movements, there was something of an obsession with these lists. This habit continued in the philosophical schools, such as the School of Logic (Nyāya), the School of Categorization (Sāōkhya) and the School of Particulars (Vaiśeṣika).

After the early suppositions of a god creating the universe in separating the earth from heaven, or something nonexistent willing itself into existence, we find that the large segments of population in India becoming Vaiṣṇavite adopted an evolutionary scheme that most identify with Sāōkhya teachings (see Sāōkhya). The Sāōkhya school vacillated between the numbers two and three: there exists only the material stuff and consciousness, yet the material stuff is of two kinds - undifferentiated, when unmanifest, and manifest when created into separate entities - so together with consciousness we get a list of three. The primeval material stuff is undifferentiated until it is disturbed. Once disturbed, it evolves into twenty-three primal entities, from which the world is formed. According to Sāōkhya, in containing these primal entities within itself in the pre-existent form, the cause contains the effect (see Causation, Indian theories of §3). A distinct entity, consciousness (*puruṣa*), brings about the initial disturbance in the primeval material stuff (*prakṛti*). The exact manner in which this disturbance is effected, or what is the relation of consciousness to this material stuff, has never been satisfactorily explained.

Twenty-three primal entities evolve from the primeval material stuff. These are all material, even though the initial ones comprise what we ordinarily consider to be our mental faculties: reason, ego and mind. Consciousness makes these otherwise material entities conscious through its 'proximity'. These first three entities are followed by five sense faculties, five action faculties, five subtle elements and five gross elements. These evolved parts, the material stuff, together with consciousness comprise everything there is.

But what accounts for the differences among entities within the world, some of them light and active and others heavy and dull? The answer is that the primeval material stuff is composed of three elemental forces: 'intelligence', energy and inertia. Different combinations of these forces account for the differences among worldly things. None of the forces is ever found by itself. Each exists only in different combinations with the others, separating and recombining in differing degrees.

3 Later Hinduism

In the later Hindu tradition, the gods become responsible for the process of the creation of the universe, and its destruction in order to create it again. This is one of the major themes of the Purāṇas. The Purāṇas ('Old Stories'), composed from about the fourth century AD onwards, centre around the creation and dissolution of the universe, time periods and genealogies. They are actually the second round of so-called 'old stories', the first one being collected in the epic of the *Mahābhārata*.

In contrast to the diverse early ideas of the universe, its arrangement and timescale, the Purānic ideas reflect a

synthesizing effort to organize the material into some kind of coherence. There is still no single creation myth, but instead we can recognize several major themes, such as the creation scheme involving *puruṣa* and *prakṛti*. This pair is responsible for the creation of whatever exists. Another theme is that of the universe as an egg. A third theme is that of a god, whether Viṣṇu, Puruṣa or Brahmā, often depicted with very human features, who creates this universe.

The interaction between *puruṣa* and *prakṛti* is often interpreted in terms of an interaction between a male and a female. This produces an egg, but it does not break open to give life; rather the universe comes alive within the unbroken egg. It has seven heavens, where the gods and some higher beings spend their allotted time. The egg also contains seven nether worlds, the dwelling place of the ogres (*asuras*) and other fantastic beings. These nether worlds are lavish places with graceful gardens and comfortable houses. Between the heavens and the nether worlds is the earth. India, the ancient name for which was ‘Jambudvīpa’, is in the centre, surrounded by six other lands, with Mount Meru as the *axis mundi*. It seems that this is all the spatial arrangement there is of the physical world. Hells are described vividly in terms of various punishments, but they do not have a physical existence and appear to be moral spaces. Neither the heavens nor the hells are permanent dwelling places. After one’s merit or demerit is exhausted, the next stop may be in the opposite quarter.

The moral aspect of this cosmology is also reflected in the four ages: *kṛta*, *treta*, *dvāpara* and *kali*. These were the terms used for the throws of a popular dice game much enjoyed at the time. The four ages, which constitute one of several theories of time, are described as involving a gradual loss of grace for humankind. The earliest period, *kṛta*, is posited as the ideal state, the past golden age. Things deteriorate in each successive age, until the fourth age, our present, in which we are more or less miserable. A favourite illustration is the cow or the bull of *dharma*, which stands on all four legs in the golden age of *kṛta*. In each successive age, the cow stands on one leg less, becoming less secure as time goes on. In our time, she stands on a single leg and thus has a hard time standing up at all.

There are other theories of time. One is a calendar, based on observations of the moon and sun, that divides time into days, months and years. This calendar has a magnified counterpart in the lifetime of Brahmā. He is the ultimate creator of the universe and his lifetime, a complicated maze of calendars, spans 12,000,000 divine years. Each divine year is 360 human years. So Brahmā’s lifetime is 4,320,000,000 earthly years. At its end, the universe dies too. This is the dissolution of the universe before its new creation, a cycle that repeats itself endlessly and is referred to as the pulsating universe.

4 Buddhism

Originally, questions about the beginning and the functioning of the world were not considered relevant in Buddhism. Whenever he was asked about such topics, Lord Buddha refused to discuss them, referring to them as vain and useless intellectual endeavour. They did not contribute to liberation.

During the next few centuries, these questions gave rise to speculations and theories which form the basis for the Ābhidharmika schools of Buddhism. Vasubandhu (fourth century AD) examines them in his monumental *Abhidharmakośa (Compendium of Abhidharma*, that is, of theories beyond the teaching of the Buddha). In the third chapter, he describes the world, the universe and the levels through which an accomplished spiritual being will pass on the way to *nirvāṇa*.

Vasubandhu believed in a Single Circular System. At the centre of the universe is Mount Meru. Past this are another seven mountain ranges, all of gold and all circular. Beyond these there are four islands. Yet another mountain range encircles all of this. There are bodies of water between each of the mountain ranges. All but the last consist of fresh water; the last one is salt water. Below Jambudvīpa (India) are the sixteen hells. At the summit of Mount Meru are the thirty-three gods.

If we shift to a nonlocational arrangement, there is a threefold division: the sphere of desire, the sphere of form, and the formless sphere. The sphere of form is further subdivided into four meditational levels. In the formless sphere the beings themselves have no form. Liberation takes place beyond the formless sphere. These three spheres are the different levels in meditation that gradually cultivate the aspirant for the final goal of *nirvāṇa*. This is a vision of a physical universe mixed with a universe known through meditation.

There are other systems in addition to the Single Circular System. We can speak basically of two major types of

cosmology: single-world cosmology, and systems based on the coexistence of multiple worlds. These cosmologies are best viewed as conceptualizations of liberation, as reflected in the different schools. In the single-world cosmology, the mechanism for rebirth involves effort, but can be manipulated: it is possible to avoid hell and go instead to heaven by doing meritorious actions. *Nirvāṇa* is liberation from a single-world cosmology, and is often described as being above the formless heavens (of the nonlocational arrangement). In multiple-world cosmologies, liberation is interpreted differently. It is rebirth in a celestial Buddha's Pure Land. This rebirth is the last rebirth, during which it is possible to attain enlightenment just by listening to Buddha's teaching.

5 Jainism

The Jainas took a keen interest in cosmography, the depiction of the organization of the universe, in order that the destinations of individuals according to their behaviour could be explained. The universe depicted was a representation of mental states experienced in meditational practices, rather than of actual or imaginary physical locations. An important source for the study of Jaina cosmography is Umāsvāti's *Tattvārthasūtra*, of around the fourth to fifth centuries AD. Chapters three and four describe the Jaina universe in painstaking detail.

The Jaina cosmology excludes cosmogony because there is no beginning of time, no beginning or creation of the universe. Time is eternal. Frequently the universe is pictured as a woman, with arms bent outward, although sometimes it is depicted as a male figure. Just as in the Hindu cosmography, the earth is in the middle of the universe. The island of the earth is divided into two parts by two mountain ranges extending north to south. There are two Mount Merus, one in the east and one in the west. Below the earth are the hells, which get progressively wider towards the bottom. The heavens, which are above the earth, first become wider (the arms bent outward), then further on they become narrower. Space, as opposed to time, is finite. The inhabited universe (*loka*) is delimited first by thick air, then by thin air, and finally is surrounded by the uninhabited universe (*aloka*), which is empty of anything. Above the heavens, in a circular region, the liberated selves bask in bliss.

This entry has given representative samples of the major trends in Indian cosmological and cosmogonic thought. There is a large body of literature that deals with a number of other things, but contains many ideas that can be considered cosmology. The *Mahābhārata*, the Purāṇas, and the Mānava Dharmaśāstra are almost inexhaustible sources for the Hindu cosmologies and cosmogonies. As compared to the random, organic growth of cosmological ideas in Hinduism, both the Buddhists and the Jainas formulated their cosmological theories after their traditions were well established, and so they reflect a more deliberate ideology.

Counterfactual conditionals

'If bats were deaf, they would hunt during the day.' What you have just read is called a 'counterfactual' conditional; it is an 'If…then…' statement the components of which are 'counter to fact', in this case counter to the fact that bats hear well and sleep during the day. Among the analyses proposed for such statements, two have been especially prominent. According to the first, a counterfactual asserts that there is a sound argument from the antecedent ('bats are deaf') to the consequent ('bats hunt during the day'). The argument uses certain implicit background conditions and laws of nature as additional premises. A variant of this analysis says that a counterfactual is itself a condensed version of such an argument. The analysis is called 'metalinguistic' because of its reference to linguistic items such as premises and arguments. The second analysis refers instead to possible worlds. (One may think of possible worlds as ways things might have gone.) This analysis says that the example is true just in case bats hunt during the day in the closest possible world(s) where they are deaf

1 Classification issues and familiar logical connectives

'Counterfactual' conditionals serve to summarize hypothetical reasoning and to justify or explain action and inaction ('I didn't tell you because, had I told you, everyone in the office would have known'). They serve to state particular causal contingencies ('If the battery were flat, the starter would not turn') and various kinds of necessity ('If he were dead, she would be a widow'). Counterfactuals have also been enlisted for philosophical analyses of dispositions ('*X* is soluble just in case it would dissolve if it were immersed in water'), causality ('Had *A* not occurred, *B* would not have occurred'), freedom of action ('I would have acted otherwise if I had so chosen'), knowledge ('If *p* were false, Mary would not believe that *p*') and laws of nature, which have been characterized as generalizations that are not merely true but support counterfactuals.

Counterfactuals are commonly contrasted with indicative conditionals (see Indicative conditionals). The following pair conveys a feeling for the difference:

(1) If Shakespeare hadn't written *Hamlet*, then someone else would have (counterfactual).
(2) If Shakespeare didn't write *Hamlet*, then someone else did (indicative).

Instead of 'counterfactual conditional', sometimes the term 'subjunctive conditional' is used. The former refers to a property of the statement made by uttering a conditional sentence in an appropriate context, the latter refers to the grammatical form of the sentence uttered. Neither label is satisfactory. A problem with 'counterfactual' is that not all assertions of counterfactuals are, or are meant to be, counter to fact, as, for example, 'If you did the cooking, I would clean up afterwards' (put forward as a suggestion before the cooking has started). 'Subjunctive' is problematic because the grammatical form in question is not the subjunctive in English (where this form is all but extinct) nor in other European languages (where it is widely used). Moreover, 'subjunctive' contrasts with 'indicative', yet indicatives such as (3) below go much more naturally with 'subjunctives' such as (1) than with indicatives such as (2):

(3) If Shakespeare does not write *Hamlet*, then someone else will.

It is surprisingly difficult to characterize the difference between the two kinds of conditional. It is not even agreed at which linguistic level - morphosyntactic, semantic or pragmatic - the distinction is to be drawn. We will content ourselves here with defining counterfactual *sentences* as the likes of (1) above. Our question is then which *statements* these sentences normally serve to express.

In the view of most authors, an analysis must state non-circular and informative truth-conditions. It should also be 'compositional': the truth-conditions of '$A \rightarrow B$' should be a function of the truth-conditions of *A* and *B* (see Compositionality). (Read '$A \rightarrow B$' as 'If it were the case that *A*, then it would be the case that *B*'.) The material conditional of classical logic and the strict conditional of modal logic both meet these demands, but their truth-conditions are unsuitable. A material conditional is true just in case either its antecedent is false or its consequent true. Since most counterfactuals have false antecedents, they would come out true irrespective of their consequents if they were treated as material conditionals. But many are not true (for example, (1) above); hence the material conditional cannot be the right analysis. A strict conditional is true just in case the corresponding

material conditional is necessarily true, or, in possible worlds parlance, just in case in all worlds in which the antecedent is true the consequent is also true. If the material conditional is too easy to satisfy, the strict conditional is too hard. Consider

(4) If fewer people smoked, fewer would contract lung cancer,

which is true if any counterfactual is. Yet there are possible worlds where the antecedent is true and the consequent false, for example, worlds in which lung cancer is caused by eating chocolate. So the strict conditional is too strict. We might confine our attention to less exotic worlds; ones governed by the same natural laws as the actual world. But that still would not do because among the lawful worlds where fewer people smoke there are worlds where more people work in coal mines and the overall incidence of lung cancer is the same. The worlds in which we are interested must resemble the actual world more closely. We imagine that fewer people smoke in these worlds, but that otherwise things are very much as in the actual world. It is this idea of a minimal departure from actuality (or purported actuality) that underlies, in one form or another, all theories of counterfactuals.

2 The metalinguistic view

Nelson Goodman (1954) put forward an influential view in which ‘ $A \rightarrow B$’ is true if and only if (1) there is an appropriate subset of all the true initial conditions that, in conjunction with *A* and the laws of nature, entails *B*; and (2) there is no other subset of the initial conditions that in the same manner entails not-*B*. The minimal departure from actuality lies in the appropriate choice of initial conditions. Two problems beset Goodman’s proposal: the characterization of the relevant initial conditions and the definition of laws. The second problem is serious, but not as serious as the first.

Apart from being true, the relevant initial conditions must be jointly compatible with *A* (as long as *A* is consistent), for otherwise any consequent whatever could be inferred and the corresponding counterfactual would be true. The conditions must also be compatible with not-*B*, for otherwise *A* and the laws would play no role in the inference to *B* - *B* would follow from the initial conditions by themselves. (‘Compatible’ statements are ones which do not jointly entail a contradiction.) But compatibility alone is not a strong enough condition. Consider

(5) If match *m* had been struck, it would have lighted.

Let $O =$ ‘oxygen is present’, $D =$ ‘*m* is dry’, $S =$ ‘*m* is struck’, $L =$ ‘*m* lights’ and $N =$ ‘If *O*, *D* and *S*, then *L*’ (our natural law). Suppose that we start with the situation of *O*, *D* and *N* being true and that the match has not been struck and has not lighted. *O*, *D* and *N* are jointly compatible with *S* and jointly compatible with not-*L*, and together with *S* they imply *L*. Therefore (5) should be true.

However, not-*L* is also true, not-*L*, *O* and *N* are jointly compatible with *S* and jointly compatible with *D*; and *O*, *N* and not-*L* together with *S* imply not-*D*. Thus

(6) If match *m* had been struck, it would not have been dry

should be true as well. This is unacceptable. Hence logical compatibility is not enough. The relevant conditions must be jointly tenable or ‘cotenable’ with the antecedent. (*B* is said to be cotenable with *A* if it is not the case that *B* would be false if *A* were true.) In this case, not lighting is compatible with, but not cotenable with, striking, because, had *m* been struck, it would have lighted; so (5) is true and (6) is not. But now we are caught in a circle or regress because cotenability is defined in terms of counterfactuals, while counterfactuals are defined in terms of cotenability. Goodman saw no way out of this quandary.

3 Possible worlds semantics

In the 1960s, modal logicians turned talk of possible worlds into a powerful analytic tool. Robert Stalnaker and David Lewis applied it to the analysis of counterfactuals. Both saw counterfactuals as devices to locate the actual world within a certain similarity structure in logical space. The intuition they built on is that ‘ $A \rightarrow B$’ is true in the actual world just in case *B* is true in the most similar *A*-world(s) (an *A*-world being a world where *A* is true). Stalnaker (1968) represents the minimal departure from actuality by a selection function on possible worlds, Lewis (1973) by ordering worlds so that given any two worlds *u* and *v*, either *u* is more similar to the actual world than *v*, or vice versa, or else *u* and *v* are equally similar to the actual world. For Stalnaker, ‘ $A \rightarrow B$’ is true if and only if

B is true at $f(A, w^*)$, the world picked out by applying the selection function *f* to antecedent *A* and the actual world w^*. *f* selects a world in which *A* is true and which, intuitively, resembles w^* as closely as the truth of *A* permits. For Lewis, '$A \to B$' is true if and only if either there is no *A*-world, or some *A* & *B*-world is more similar to the actual world than any *A* & not-*B*-world. Lewis' analysis makes '$A \to B$' trivially true when *A* is impossible, which is when there is no *A*-world. So does Stalnaker's analysis because, for impossible *A*, *f* selects 'the impossible world' in which every statement is true.

An argument form is valid if and only if it has no instance with true premise(s) and a false conclusion. The following is an example of an invalid argument:

If Ronald Reagan had been born a Russian, he would have been a communist.
If he had been a communist, he would have been a traitor.
Therefore, if he had been born a Russian, he would have been a traitor.

The premises seem true, but not the conclusion. The argument is an instance of 'hypothetical syllogism':

$A \to B, \quad B \to C \quad \therefore\ A \to C$

The possible worlds theory explains how hypothetical syllogism can fail to be valid. World *c*, the closest world where Reagan was a communist, is closer to the actual world than world *r*, the closest world where he was born a Russian. In *c*, his career is as we know it, except for that traitorous affiliation. In *r*, he grows up in Russia, becomes a loyal party member there and never dreams of being president of the USA. So *c* makes the second premise of the argument true, while *r* makes the first premise true and the conclusion false.

On the Lewis-Stalnaker analyses, a number of argument forms that are valid for the material and various strict conditionals are invalid. Hypothetical syllogism is only one of them. Others are:

$A \to B \therefore\ \text{not-}B \to \text{not-}A$ ('contraposition')
$A \to B \therefore\ C \to B$, where C entails A ('strengthening the antecedent')
$A \to (B \to C) \therefore\ (A\ \&\ B) \to C$ and
$(A\ \&\ B) \to C \therefore\ A \to (B \to C)$ ('import-export')

For practical purposes, the invalid argument forms can often be replaced by similar valid ones, for example, hypothetical syllogism by

$A \to B, \quad (A\ \&\ B) \to C \quad \therefore A \to C.$

The distinction between valid and invalid argument forms ought to match natural language usage. Examples like the one about Reagan therefore carry heavy weight. If they were rejected and any of the argument forms in question added to the logics that emerge from the Lewis-Stalnaker analyses, '$\to$' would collapse into the material conditional. Attacks on the counterexamples are therefore indirect attacks on the core of the analyses. (For more discussion, see Stalnaker 1984.)

4 Similarity

Lewis allows ties in the relative similarity between worlds, as well as no limit to how closely worlds can resemble each other. Stalnaker's theory can be seen as a special case of Lewis' that does not make these allowances. For Stalnaker, there is to be always exactly one most similar antecedent-world. The difference is reflected in a disagreement about the principle of 'conditional excluded middle' which says that '$A \to B$' and '$A \to \text{not-}B$' cannot both be false. The principle holds in Stalnaker's view but not in Lewis'. In Lewis' view, there may be, for any *A* & *B*-world, an equidistant or closer *A* & not-*B*-world and vice versa, so that both counterfactuals can be false. For Stalnaker, there is exactly one closest *A*-world in which either *B* or not-*B* is true. Consider the pair

If Bizet and Verdi had been compatriots, Bizet would have been Italian.
If Bizet and Verdi had been compatriots, Verdi would have been French.

We hesitate to affirm either. Doesn't this show that Lewis is right? Not necessarily. We also hesitate to deny either of the two, and the best explanation may be that the relevant standard of similarity between worlds has not been

made clear, so that we do not know exactly what claims are at issue. Conditional excluded middle holds relative to a given selection function *f*, but it does not apply to cases where *f* has not been determined. Any theory of counterfactuals must allow for a good measure of indeterminacy if it is to account for actual usage.

Goodman's theory can be transposed into the possible worlds framework. With the right definition of cotenability, it becomes equivalent to Lewis'. Does Lewis therefore solve Goodman's problem about cotenability? In some sense, yes, because there is no longer a circle in the truth-conditional schema. In another sense, no, because Goodman's worry was less about the abstract form of the analysis than about how particular cotenability judgments can be grounded. For an answer to this question, the notion of relative similarity between worlds is probably too vague.

The relevant notion of similarity cannot be the one we use when we compare ordinary objects. For otherwise we should reject

If Nixon had pushed the button, there would have been a nuclear holocaust,

because among the worlds where Nixon pushes the ominous button those where nothing happens are more similar to ours, in the everyday sense of similarity, than those where the doomsday machinery goes off. But given that there is (or was) such a button, the counterfactual looks true. Lewis suggests that the similarity relation relevant for counterfactuals has the most similar worlds agree with the actual world throughout the past until shortly before the time of the antecedent. Then a small miracle (a deviation from the laws of the actual world, not from those of the world in question) brings about the antecedent, and from then on history evolves in accordance with the laws of the actual world. The proposal has limited scope. It does not apply to 'counterlegals' about what would be the case if this or that law of nature were different. It also does not deal with disjunctive antecedents pertaining to different times. Maximizing agreement throughout the past would naturally lead here to a selection of worlds in which only the disjunct pertaining to the latest time holds. Other authors favour total agreement in laws over miracles of any size. Miracles prevent a counterfactual extrapolation of what the past would have had to have been in order to bring about the antecedent. Yet such 'backtracking' is perfectly intelligible. Jim and Jack quarrelled yesterday and Jack is still furious. If Jim asked a favour of Jack today, Jack would oblige him none the less. For in order that Jim ask, there would have had to have been no quarrel before. The significance of backtracking and Lewis' proposal about similarity remain contested.

5 Comparisons

Metaphysical and other qualms about the possible worlds analyses rekindled an interest in metalinguistic theories in the 1980s. There have also been proposals for an epistemic analysis based on the idea that '$A \rightarrow B$' is 'acceptable' with respect to a body of beliefs *K* just in case *K*, minimally changed so as to accommodate *A*, entails *B*. Formally, most of these theories are equivalent to Lewis' or slight variants thereof, but they avoid the ontological cost of possible worlds. In so far as they do not provide truth-conditions, the epistemic theories have difficulty explaining the role of counterfactuals embedded in truth-conditional constructions such as conjunctions or disjunctions. Moreover, the idea of revising a body of beliefs seems better suited for evaluating indicative conditionals than counterfactuals. For example, if you add to your present beliefs the assumption that Shakespeare did not write *Hamlet* and make the minimal changes necessary to restore consistency, you will infer that someone else must have written the piece because you have no reason to give up your belief in its existence. This yields the correct judgment for the indicative (2) but not for the counterfactual (1). It is not obvious how to adapt procedures of belief change to counterfactuals.

Goodman and many others believed that an analysis of counterfactuals was indispensable for the philosophy of science. Few still share this opinion. The cotenability problem, the indeterminacy of many counterfactuals, and doubts about possible worlds and their similarities have convinced many that counterfactuals do not belong in the ultimate scientific description of the world. In decision and game theory, by contrast, the peculiarity and importance of counterfactual reasoning has only just begun to be appreciated. The solution of decision problems requires answers to questions about situations that, as a result of the very decision at issue, will be counterfactual. Counterfactuals also continue to play an important role in philosophical analyses, and their use and misuse in daily commerce is largely unhampered by difficulties of interpretation.

Cournot, Antoine Augustin (1801-77)

Cournot is best known for his work in applying mathematical techniques to economic and social affairs and is generally acknowledged to be the founder of econometrics. His work in philosophy, however, is at least as distinguished. His philosophy may be seen as a meditation on continuity and discontinuity, on law and brute empirical fact, which is unassimilable to law. Empiricism is exclusively preoccupied with the latter phenomenon, rationalism with the former. Cournot affirmed the reality of both. His philosophy thus mediates between empiricism (which, when it is consistent, leads on his view to scepticism) and rationalism (which, when it is consistent, loses contact with reality).

Continuity is real because the world is not a chaos; it is a network of events, forming various series, which reveal necessary and determinable relations. But discontinuity is also real, for the order we discern in the various events is not a single order. The series are independent and the points where they intersect cannot be predicted from within the series themselves. Brute contingency is therefore as real as law. Consequently, though the world may be known, it can never be reduced to a single scheme.

Antoine Augustin Cournot was born in the town of Gray, near Dijon. He was raised in his grandmother's house, being especially influenced by an uncle, who was a Jesuit, and by a maiden aunt, whose views were directly opposed to those of the uncle. At an early age, he learned to balance different views, to form his own conclusions, and to keep his peace. He was educated at Gray and at the École Normale in Paris, specializing in mathematics and science. He spent his working life in the university, holding chairs at Lyons and Grenoble. In 1838, he was named Inspector General and in 1854 was appointed as Rector of the Academie at Dijon. Involved in teaching and administration, he continued to work on fundamental problems in many fields. In 1851, he published his most important philosophical work, *Essai sur les fondements de nos connaissances (An Essay on the Foundations of Our Knowledge)*. Failing eyesight led to his retirement in 1862. But he continued to work at philosophy and in his last years published another important work, *Matérialisme, Vitalisme, Rationalisme (Materialism, Vitalism and Rationalism)*.

Like Kant, Cournot held that knowledge is relative. We know the world not in its ultimate nature but in its relations to ourselves. Cournot, however, rejected what he took to be Kant's subjective idealism, denying that the order we discern in nature is the product of our own minds. The central problem in philosophy is precisely to clarify how the mind makes contact with reality through its grasp of order. Empiricism is inadequate for this purpose, for the senses serve neither as the basis nor as the criterion for knowledge. A simple example will illustrate the point. Consider a law, such as Boyle's law, which is consistent with numerous observations. The observations, however numerous, are a random selection from those that might be made. They represent an element of chance. We accept Boyle's law because we cannot believe that under those chance conditions the law would always be confirmed, unless it represented an order in the gases which is independent of the conditions themselves. It is not the observations which explain the law; it is the law which provides the best explanation for the observations. The point is evident on other grounds. First, observations, being discontinuous, cannot correspond to law, which is continuous; a law holds, whatever the observations. Second, with sufficient ingenuity one can think of many different laws which are consistent with those same observations. Science, according to Cournot, depends on a feeling for order which cannot be quantified and which is akin to the feeling for beauty.

Law in itself, however, is not sufficient for knowledge. The laws of planetary motion will enable us to fix the positions of the planets at any time in the future or the past. But suppose, in the remote past, a comet entered the planetary system, disturbed its arrangement and then disappeared. No trace of this event would appear in our knowledge of astronomy. Consequently, in fixing the positions of the planets, prior to its occurrence, we should be led into systematic error. It is impossible to believe that such events have never occurred. Much in history, therefore, is likely to be not simply unknown but unknowable. In short, scientific rationalism is as inadequate as empiricism.

Cournot anticipated Darwin's theory of evolution (see Darwin, C. §§2-3). He discussed what is virtually the same theory, in his *Essay*, some eight years before Darwin's work appeared, arguing that it could not provide a comprehensive explanation of the evolutionary process. He agreed that the environment has an important role in

selecting organic forms for survival. What the theory cannot explain, however, are the organic forms themselves, which cannot evolve through an accumulation of chance variations. Each organic form is an order, involving an interrelation of its parts. The forms therefore are discontinuous; to get from one to another through continuous variation one would have to pass through stages which do not constitute possible organic forms. Thus a wing which is slightly too weak for flight is entirely useless as a wing. The evolutionary process can be understood only as a phenomenon involving both continuity and discontinuity, order and chance. The pattern of a leaf is definite, so far as its principle veins are concerned, but, in its ultimate ramifications, is so modified by contingent forces that no individual leaf is exactly the same as another. Similarly, the world itself is governed by general laws the detailed fulfilment of which is left to contingent circumstances. Consequently there is no conflict between contingency and finality or purpose. It is through contingency that finality or purpose works. Thus it is not in order to serve the needs of the bee that the flower exists. The flower exists for its own sake, exhibits finality in itself, and simultaneously serves the needs of the bee. For Cournot, the world is a composition, overwhelming in its beauty and complexity, which is executed simultaneously on different planes.

Cousin, Victor (1792-1867)

French philosopher, educationalist and historian, Victor Cousin is primarily associated with 'Eclecticism' and the history of philosophy, but his work also includes contributions to aesthetics, philosophy of history and political theory. He was a prolific writer and editor, and a significant figure in the development of philosophy as a professional discipline in France.

Victor Cousin was born in Paris, the son of an artisan. His education was funded by a wealthy sponsor, and culminated in the prix d'honneur and study at the École normale, where his formative influences included Laromiguière, Royer-Collard and Maine de Biran. His subsequent academic career at the École normale and the Sorbonne progressed rapidly, his lectures attracting large audiences and much publicity. In the early 1820s Cousin became a victim of the reaction against liberalism; his university lecturers were suspended and the École normale closed. Employed as a private tutor, Cousin worked on the history of philosophy and studied contemporary German idealism. On a visit to Prussia in 1824, French police reports and his association with members of the Carbonari led to his imprisonment. Hegel, with whom Cousin had established a relatively warm association, intervened on his behalf with the authorities, and he was subsequently released. Restored to his University post in 1828, Cousin's lectures received great acclaim and, especially under the July Monarchy, public recognition followed on a grand scale. He became a member of the Académie Française and of the Académie des Sciences Morales et Politiques, a peer of France, Commander of the Légion d'Honneur, member of the Conseil Supérieur de l'Instruction Publique and, briefly, in Theirs' second cabinet, minister for public instruction. From 1830, Cousin increasingly devoted his energies to administrative and educational affairs. Using his position as director of the École normale, he presided over the development of philosophy as a professional (and non-theological) discipline in France. Cousin also influenced the reform of French primary education, publishing reports on the school systems of Prussia, Saxony and Holland. Following the 'tragic experience' of 1848, he fell out of favour, and with the coup d'état of 2 December 1851, was increasingly removed from public life. His last years were spent quietly, surrounded by his books in rooms in the Sorbonne, writing a series of historical studies, mainly portraits of women notables of the seventeenth century. He died in Cannes.

Cousin was probably the best known exponent of Eclecticism, maintaining that schools of philosophical thought (which, for him, fell into four categories) all contained elements of the truth that, once recovered, could be reconciled. Sensationalism, idealism, scepticism and mysticism, he averred, were 'not false but incomplete'. Cousin denied the charge of facile syncretism, insisting that Eclecticism was grounded in a tripartite model of human psychology revealed by observation and experiment, human nature being composed of the three distinct but complementary faculties of sensibility, will and reason. Various philosophical schools were chided for their neglect of one or more of these capacities; thus Cousin charged the epistemology of Condillac (and of his materialist successors) with mistakenly reducing human experience to the passive faculty of sensation.

For Cousin, the reason revealed by psychological introspection was universal and necessary, and by virtue of this impersonal character - and in a manner not always clear to his critics - it provided the conditions for both the existence of, and our knowledge of, humanity and nature. His apparent assertion of the immanentism of reason led to charges of pantheism or even Neoplatonism (see Pantheism; Neoplatonism). Clerical critics were scarcely reassured when Cousin insisted that, since the masses could not attain philosophical understanding, his system preserved a place for religion as a socially necessary and seemingly inferior (because symbolic) parallel of Eclectic metaphysics.

Art (like religion and philosophy) was a mode in which the infinite, or God, became apparent. It formed an independent sphere in which human nature provided the criteria by which to judge an ideal beauty. For Cousin, the aesthetic hierarchy that resulted was headed by imaginative poetry.

Cousin also discerned a 'manifestation of God' in the historical development of epochs and cultures. History followed a tripartite spiritual progression, as philosophical concerns turned from the infinite, to the finite, to the relation between the two. The resulting Oriental, Greek and Modern worlds were characterized successively by pantheism (and monarchy), polytheism (and democracy), and theism (and constitutionalism). Cousin described this philosophy of history as both speculative and empirical, although critics found it easier to discern evidence of the

former than the latter quality. Furthermore, here as elsewhere in Cousin's work, the distinction between his own opinions and his reproduction of certain themes in contemporary German philosophy is not always apparent.

In rejecting all exclusive doctrines, Eclecticism claimed to have a political parallel in the repudiation of political doctrines and practice based on faction. Cousin was a moderate liberal, committed to constitutional monarchy, the Charter and the interests of the 'juste milieu'. He distinguished a sphere of enforceable individual rights to equal respect and private property, and a subordinate sphere of voluntary duties to protect and promote the wellbeing of others. Cousin attributed a positive role to the state, not least in the provision of moral and educational instruction.

Claiming to recover and reconcile the truth embedded in previous schools of thought, Eclecticism encouraged work in the history of philosophy. Cousin's own efforts in this area were prodigious. His editorial labours included a six-volume edition of Proclus (1820-7); an eleven-volume edition of Descartes (1826); and single-volume editions of Abélard and Maine de Biran. Cousin was also responsible for a thirteen-volume translation of Plato (1822-40). His interpretative studies included works on Aristotle, Locke, the Scottish Enlightenment and Kant, together with an inflammatory contribution to *l'affaire Pascal* (an acrimonious dispute about editorial and interpretative standards in contemporary Pascal scholarship).

The contrast between Cousin's intellectual hegemony in nineteenth-century France and the subsequent neglect of his work is striking. Although Cousin's historical significance is undeniable, claims for the intrinsic philosophical interest of his work remain muted. Eclecticism strikes many as empty or flawed, while Cousin's role as an interpreter and popularizer of post-Kantian German philosophy largely rests on the unsystematic, and often unacknowledged, incorporation of elements of Schelling and Hegel into his own work. Even Cousin's endeavours in the history of philosophy, although not without interest, and unquestionably important in opening up French philosophy to new influences, frequently fall short of modern scholarly standards.

Crathorn, William (*fl. c.*1330)

An English scholastic a generation younger than William of Ockham, Crathorn's theological writings confront the central metaphysical and epistemological problems of his day. He is of interest largely because of his willingness to pursue the logical implications of his views to the most extreme conclusions. This characteristic makes Crathorn a provocative and idiosyncratic thinker, although not always a coherent one.

Crathorn was a Dominican friar from northern England who lectured at Oxford on Peter Lombard's *Sentences* during the academic years 1330-2 (see Lombard, P.). These lectures, his *Quaestiones in primum librum Sententiarum (Questions on the First Book of the Sentences)*, are our best guide to Crathorn's philosophy. In them he discusses the most controversial philosophical problems of his day, such as divine foreknowledge and human freedom, the ontological status of the Aristotelian categories and the distinction between intuitive and abstractive cognition. His philosophical agenda owes much to William of Ockham, but he is not in any sense Ockham's disciple; at almost every juncture Crathorn explicitly rejects Ockham's views.

Crathorn's theory of universals, developed in his *Quaestiones*, is central to his thought. He begins by rejecting competing views, including those of Thomas Aquinas and John Duns Scotus as well as Ockham's early *fictum* account. Crathorn's treatment of Aquinas, a fellow Dominican, is particularly interesting. After faithfully describing what Aquinas said about universals, Crathorn denies that this was what Aquinas actually meant. Perhaps, Crathorn suggests, Aquinas advanced such a view 'by way of conforming himself to the way men of his time spoke'. Evidently, any pressure that Crathorn may have felt to adhere to the views of his great *confrère* was not enough to force a substantive change in Crathorn's own thought.

At first glance, Crathorn's own theory of universals appears to be a rather ordinary nominalism. A universal, he says, is anything that either causes, resembles or is conventionally predicated of more than one thing. Only words and concepts can be universals in the ordinary sense of the term. Words can be universal in the third way: by convention, they are predicated of more than one thing. Concepts can be universals in either the second or the third way.

It is here that the peculiarity of Crathorn's position emerges. How can concepts either resemble or be conventionally predicated of external things? The first of these may seem less peculiar, since most scholastics spoke of mental representation in terms of similarity. However, Crathorn is unique in holding this doctrine in a completely literal way. For him, the concept of whiteness really is white. He in effect asks how anything could resemble what is white otherwise than by being white (*Quaestiones* q.1, concl.7). But Crathorn does not hold that all concepts are likenesses of this sort; he notices, for instance, that there is nothing in the external world for the general concept of colour to resemble (*Quaestiones* q.11, concl.4). Here Crathorn faces a problem. Whiteness, like colour, is a determinable property, so there is no one shade of white in the external world for the concept 'whiteness' to resemble. In fact, however, Crathorn does find something in the external world for non-determinate concepts like 'colour' to resemble: they resemble (again, literally) the written or spoken words used to express that concept. Thus our concept of colour is literally a likeness of the word 'colour'. Crathorn says that this concept is conventionally predicated of colours inasmuch as it resembles the word 'colour', which is itself conventionally predicated.

Crathorn explicitly holds that these concepts are the immediate objects of intellective cognition. Likewise, sensory impressions are what we immediately perceive, and they, too, literally resemble features of the external world. This leads him to confront the notorious sceptical problem of how we know anything about the external world if all we directly perceive is internal impressions (see Scepticism). At the outset of his commentary, Crathorn develops on this basis a series of ever more serious sceptical conclusions, culminating in the claim that on the basis of our sensory impressions alone we can have no knowledge of the external world. However, Crathorn averts an epistemological crisis by appealing to the knowledge, available to us a priori, that God would not let us be deceived in this way - at least not regularly.

According to his contemporary and rival Robert Holcot, Crathorn later publicly lectured on the Bible, but no record of these lectures has been found. Richter (1972) describes a manuscript containing what purports to be

quodlibetal questions by Crathorn; some of these questions are from the *Quaestiones*, others not. This additional material, largely philosophical rather than specifically theological, has been neither edited nor studied.

Cratylus (late 5th/early 4th century BC)

Probably an Athenain, Cratylus was a radical Heraclitean, holding that the world is in constant and total flux. Through this doctrine he had a seminal influence on Plato. Cratylus also, for some time at least, defended the natural correctness of names.

Taking ’Everything is in flux’ to be the core of Heraclitus’ philosophy (see Heraclitus §3), Cratylus concluded (Aristotle, *Metaphysics* 1010a9) that Heraclitus was wrong to deny the possibility of stepping twice into the same river: total flux excludes stepping into the same river even once, and it also implies that one should say nothing. Accordingly, Cratylus ‘finally’ disavowed speech and merely waggled his finger. In the words of Aristotle (Aristotle, *Metaphysics* 987a32), the young Plato ‘became familiar with Cratylus and with the Heraclitean doctrines that all phenomena are always in a state of flux, and that there is no knowledge about them’. These doctrines, Plato himself later espoused.

Both Plato and Aristotle regularly associate Heraclitus with the constant flux of everything. Some scholars take this to be a misinterpretation of Heraclitus, mediated by Cratylus, with little support in Heraclitus’ transmitted words. Yet Aristotle’s remarks about Cratylus only make sense on the assumption that Cratylus took himself to be improving the consistency and implications of Heraclitus’ own flux doctrine. Total flux excludes everything, including a river, from ever being ’the same’. The inference that nothing has an intrinsic identity if everything is in total flux is drawn by Socrates in Plato’s *Theaetetus* (156a-157c) (see Plato §15). There is also a probable echo of Cratylus’ recommendations about refraining from speech when Socrates argues that no names are legitimate that ’make anything stand still’. Plato’s dialogue *Cratylus* ends with Socrates arguing that knowledge is impossible ’if everything is changing and nothing persists’. Plato responded to Cratylus by arguing that even if total flux holds true for the phenomenal world, it does not pertain to the stable and everlasting Forms, which are the only genuine objects of knowledge.

As a linguistic naturalist, Cratylus denied that usage has any bearing on the correctness of names. All names that are really names are correct, and their correctness is due to their capacity, irrespective of particular languages, to signify the nature of things. A phonetic item that is inappropriate to the nature of the thing cannot be that thing’s name. He rejected therefore the possibility of speaking falsely. In Plato’s portrayal Cratylus, as a Heraclitean, approves Socrates’ efforts to explain the phonetics of Greek words as natural signifiers of flux even after Socrates has shown that the hypothesis cannot be valid for all names. By the time Cratylus decided to waggle his finger instead of speaking, had he abandoned this linguistic naturalism? Many have thought so, but the supposition is not necessary. Cratylus may have still believed that the only correct names must be names that reveal the nature of things. His final position was probably not the abandonment of this thesis but the inference that things in total flux have no nature that names could reveal.

Creation and conservation, religious doctrine of

The doctrine of the creation of the universe by God is common to the monotheistic religions of Judaism, Christianity and Islam; reflection on creation has been most extensively developed within the Christian tradition. Creation is by a single supreme God, not a group of deities, and is an 'absolute' creation (creation ex nihilo, *'out of nothing') rather than being either a 'making' out of previously existing material or an 'emanation' (outflow) from God's own nature. Creation, furthermore, is a free act on God's part; he has no 'need' to create but has done so out of love and generosity. He not only created the universe 'in the beginning', but he sustains ('conserves') it by his power at each moment of its existence; without God's support it would instantly collapse into nothingness. It is controversial whether the belief in divine creation receives support from contemporary cosmology, as seen in the 'Big Bang' theory.*

1 Creation and polytheism

That the universe has been created by God is one of the most fundamental tenets of Judaism, Christianity and Islam. Creation plays a key role in the theistic worldview and is rich with implications. Every major alternative confronting the theistic worldview has presented a different kind of challenge to the belief in creation. Here we consider several such challenges, taken roughly in historical order.

The biblical belief in divine creation took form in the midst of the conflict between the monotheistic faith of Israel and ancient polytheism. Particularly significant was Mesopotamia, which was both the region from which Abraham came ('Ur of the Chaldees') and the scene of the formative experience of the Babylonian exile. The creation narrative in Genesis 1 has marked parallels with the Babylonian *Enuma Elish* but the theological context and emphasis are vastly different (see Heidel 1951). Here we do not have the numerous gods in their rivalry and occasional strife, but rather the single creator God ordering all things in accordance with his Word. That God simply speaks, with effortless mastery - 'and it was so' - contrasts with the various means of creation in contemporary mythology. There is no trace in Genesis of a struggle in which the earth is fashioned out of the corpse of a slain monster, or of a divine 'begetting' in which some part of the cosmos comes from the deity by sexual generation (or vice versa). Particularly noteworthy is the treatment of the heavenly bodies, which in Babylon as in most ancient cultures were worshipped as divine. Rather than being given divine honours, they are assigned an important but strictly functional role in the creation ('to give light upon the earth, to rule over the day and over the night, and to separate the light from the darkness'); the stars are added almost as an afterthought.

2 Creator or Demiurge?

When the Christians of the second and third centuries began to reflect upon their faith in the light of Greek philosophy, one of the readily available conceptual models for creation was the one presented by Plato (§16) in the *Timaeus*, where the Demiurge in his beneficence 'desired that all things should come as near as possible to being like himself' (*Timaeus* 29e). But certain deficiencies were evident, as compared with what Christians wished to say about their God. The Demiurge is not ontologically supreme, but clearly is subordinate to the Forms. The good intentions of the Demiurge are limited and often frustrated by the recalcitrant matter with which he must work, but which he had no part in creating. In later Gnostic worldviews, the status of matter becomes even more problematic: it is evil in itself, and the fundamental source of evil in human life. The Demiurge, who has imprisoned humans in mortal bodies, is contrasted with and inferior to the High God, who seeks to liberate them from material contamination (see Gnosticism).

In opposition to this, the Church Fathers insisted that God is the supreme source of all concrete existence other than himself: he has created all things *ex nihilo*, 'out of nothing'. The idea is not, of course, that 'nothing' is the name of some negative, peculiarly elusive 'stuff' out of which creation came. On the contrary, creation *ex nihilo* means precisely that there is no pre-existing 'stuff' whatsoever - that things have come to exist solely because of the Word and creative power of God. To be sure, creation *ex nihilo* is not to be found in Genesis; the chaos of Genesis 1: 2 is not said to be created, but is presupposed in the later acts of creation. But creation out of nothing is at least strongly suggested in the New Testament (for example, Romans 4: 17, Hebrews 11: 3), was clearly affirmed by the early Church Fathers (for example, Irenaeus), and has been the consistent teaching of Christian theologians, apart from occasional lapses in the direction of emanationism (see §3). And matter, the physical

realm, is not some negative, inhibiting factor which impedes God in the achievement of his purpose; rather, it is itself created by God and is an integral part of the creation which he pronounced 'very good'.

3 Creation and emanation

Among the philosophical options offered by the ancient world, one of the most attractive to Christian thought was the Neoplatonism of Plotinus (see Neoplatonism; Plotinus §§3-5). This theory emphasized the vast difference between the transcendent God (or 'One') and the mundane realm, and urged human beings, in pursuit of their true good, to seek reunion with the divine source from which they had come. Neoplatonism furnished a rational, philosophical account of the derivation of the world from that source, one that had to be taken seriously by theologians who needed to free themselves from crude, anthropomorphic images of divine 'making'. The idea of evil as 'privation', taken from Neoplatonism, went far towards an understanding of how evil can exist in a world wholly created by God without God's having created evil. Evil, on this account, is not a positive existence in itself, but simply a deficiency in a created being which is, as created, good. And since to be created is as such to be less than God and thus subject to imperfection, there is no occasion for surprise (or for any reproach to God) in the existence of such imperfections in the creation. Finally, some of the 'emanations' from the One were fairly readily assimilated to the emerging doctrine of the Trinity, thus enhancing both the rational appeal of that doctrine and the attractiveness for Christians of the Neoplatonic philosophy.

For Neoplatonism, the fundamental concept for relating the One (that is, God) to the world is that of emanation. In general, emanationist schemes have the following characteristics:

1 God, or the One, is conceived in terms of extreme transcendence, so remote from everyday reality that he (or it) can be described only in negations.
2 God is linked to the world of everyday experience through a graded series of levels. For Plotinus, these are Mind, then Soul (itself divided into an upper and a lower aspect), and then the individual souls of humans and animals, until finally the lowest level, that of material bodies, is reached.
3 Each lower level in the series is derived from the next higher level through the process of emanation. The lower level 'flows out' from the upper level without diminishing it; illustrative analogies include the outflow of a stream from a spring, and light radiating from a lamp. Thus the lower level is inferior in ontological status, yet shares in the nature of the higher level which produces it.
4 The emanation of a lower level from a higher is eternal and necessary; it follows from the nature of the higher level, and does not involve or depend on a decision of will.

This general scheme was adopted with only minor modifications by some Christians, such as Pseudo-Dionysius and Johannes Scottus Eriugena. It was also taken over by the Muslim philosophers al-Farabi (§2) and Ibn Sina (§5). But it was rejected or severely modified by the major theologians of Judaism (see Maimonides §3), Christianity (for example, Augustine and Aquinas>) and Islam (see al-Ghazali §3; Neoplatonism in Islamic philosophy). In general, the following aspects of emanationism are objectionable from the standpoint of biblical or Qur'anic thought:

1 The extreme separation of the Source from the everyday world, and the refusal to apply ordinary predicates to it, make it problematic to equate it with the personal God of theism. In particular, the need for a series of intermediaries linking God and the world is in conflict with the biblical and Qur'anic witness to the immediate presence and activity of God in all aspects of existence.
2 On the other hand, the nature of the process of emanation threatens the fundamental distinction between God and creatures that is essential to theism. 'Creation' in this scheme is really not *ex nihilo* but rather *ex deo* - a conclusion which is hardly welcome to any of the monotheistic religions.
3 Finally, the necessary, nonvolitional character of the process of emanation undermines the freedom of God in creation, and thus also the sense of gratitude to God for the generous gift of existence he has bestowed on us and on the world.

The concept of creation, as developed by theistic philosophers and theologians, agrees with emanationism in strongly emphasizing the dependence of creatures on God. But it insists on a fundamental ontological distinction between the creator and the creatures: creation is *by* God, but not *out of* God. God bestows on creatures a being that is their own and not his, though it is always dependent upon him. Furthermore, it is insisted that creation is a

free and gratuitous act on God's part: there was and is no necessity for God to create a world. To this it might be objected that, since it is obviously better for there to be a universe than for there not to be one, a wise and good God must of necessity have created a world. The answer to this objection is rather startling: God is infinitely greater than creatures, so the value of God plus the entire creation is no greater than the value of God by himself. (Adding a finite quantity, no matter how large, to infinity still leaves you with just infinity, not 'infinity plus'.)

4 Creation as temporal or eternal?

One further question raised by emanationism is not answered by the considerations discussed above. Is creation temporal or eternal? Does the universe have a temporal beginning or is it beginningless? This question was especially acute for medieval thinkers because it was claimed that Aristotle had demonstrated the eternity of the world; on the other hand, the Scriptures seemed to point definitely towards a temporal beginning (see Eternity of the world, medieval views of). In response to this, Maimonides pointed out that even if the eternity of the world had been demonstrated, it would be perfectly possible to give a figurative interpretation of those biblical texts that seem to imply a temporal beginning. Aquinas and other Christian writers had less freedom, because the Fourth Lateran Council (1215) had defined it as a doctrine of faith that the universe had a beginning in time.

The predominant view at the time among both Christians (such as Bonaventure (§5)) and orthodox Muslims was that, contrary to the claims of the Aristotelians, the temporal finitude of the universe could be conclusively demonstrated. This was argued on the basis of certain problems with the idea of an 'actual' (already realized) infinity, such as seems to be involved in the concept of an infinite past. For example: if the past is infinite, then there has occurred a time which was an infinite number of years prior to the present. But if this were so, it would be impossible that, through the passing of years one by one, an infinite number would be traversed and we would find ourselves in the present. So if the past were infinite, the present would never have been reached, which is absurd. (This problem does not arise for an infinite future, because future eternity, unlike past eternity, is only a 'potential' infinity; there will never come a future time separated from the present by an infinite number of years.)

The response of both Maimonides and Aquinas at this point is that neither the finitude nor the infinity of the past has been demonstrated; philosophically, the question remains open. (The answer given to the argument described above was that, even if the past is infinite, it still is not the case that there exists some time which occurred an infinite number of years before the present. Any given time in the past preceded the present by only a finite number of years - and was itself preceded by an already infinite past.) Both Maimonides and Aquinas, then, were free to affirm on the basis of Scripture that the past is finite and that the world has a temporal beginning.

It is important to see, however, that the question of the world's eternity is not settled by the considerations discussed in §3 above. For suppose that, contrary to the conclusion of Maimonides and Aquinas, the world does indeed have an infinite, beginningless past. It could still be said that the universe is created *ex nihilo*, in the sense that it has no existence except that which is wholly dependent on the will and power of God. Its relation to God would then be just what theists suppose the relation to God of the actual universe to be, at every moment subsequent to the first. It could, furthermore, still be the case that God is entirely free in creating the universe - that it is simply by God's free decision that there is eternally a universe distinct from God, rather than God existing alone in self-sufficient perfection.

That is not to say that the issue of a temporal creation is religiously indifferent; there are, after all, the biblical and Qur'anic texts that seem to imply such a beginning. It is clear, furthermore, that the notion of an eternal creation strongly suggests, even if it does not logically imply, some sort of necessity for the creation process - either because God has some kind of need for a creation, or because the universe is produced from the divine nature by some sort of necessity. A belief in the eternity of creation tends towards a denial of the freedom of God in creation, even if it does not force us to that conclusion.

5 Conservation, continuous creation and deism

Belief in God as creator has almost always involved the affirmation that God not only produced the universe in the beginning, but sustains it in being from moment to moment. The New Testament says of Christ that 'in him all things hold together' (Colossians 1: 17), and describes him as 'sustaining all things by his powerful word' (Hebrews 1: 3). And the Psalms are pervaded by the sense of the immediate dependence of the creatures on their

creator: ‘When thou sendest forth thy Spirit, they are created; and thou renewest the face of the ground’ (Psalms 104: 30). So theistic philosophers and theologians have affirmed the divine conservation of creatures, claiming that no creature exists at any moment unless God actively sustains its existence at that moment; without this support it would instantly vanish into nothingness.

There has been debate, however, about the use of the phrase ‘continuous creation’ to describe this process. Descartes wrote that ‘the same power and action are needed to preserve anything at each individual moment of its duration as would be required to create that thing anew if it were not yet in existence’ ([1641] 1984: 33). But this does not seem quite correct. No doubt it is true that a being already in existence is as unable to exist without divine power as one which newly comes into existence this very moment. But it is not strictly true that God does exactly the same thing in the two cases. When he newly creates something *ex nihilo*, he brings into existence something that previously did not exist, either as a whole or in its several parts. When he conserves some being, then he sustains the continued existence of a being that is already in existence. And this point is crucial for countering the argument for occasionalism (see Occasionalism). When God newly creates a being *ex nihilo*, then God alone must determine all that being’s characteristics; there is nothing else that might perform this task. But when God conserves a being that is already in existence, then the previous state and causal powers of that being can play a part - often a large part - in determining the being’s state and characteristics at the time in question.

So it does not seem to be the case that God does exactly the same thing when he creates something anew as when he conserves it in existence. The expression ‘continuous creation’ might still be used as a dramatic way of calling attention to the fact that an already existing being has no more power to maintain itself in existence than a nonexistent and merely possible being has to bring itself into existence. But a straightforward equating of creation with conservation seems to be ruled out.

It should be noted here that most medieval theologians held that, in addition to conserving the world in existence, God ‘concurs’ in each and every instance of creaturely action. This concurrence is not mere permission, but is rather an active causal contribution by God in cooperation with the creaturely action, which apart from this cannot bring about its result. This doctrine of divine *concursus* has not played a major role in recent discussions of creation; it remains to be seen whether a convincing case can be made for it.

The deists rejected the doctrine of conservation, asking in effect why God could not create beings which, once created, could go on about their business without further direct help from him (see Deism). But the religious case for divine conservation is compelling, even aside from scriptural texts. If God did not act to conserve creatures in existence, then his present action in the world would be limited to special miraculous acts of divine intervention - a highly undesirable result, even if one has no objection to the idea of miracle as such. The religious sense of dependence upon God and of being sustained by God, an important part of the religious life for a great many believers, would have to be either rejected as illusory or radically reinterpreted. (It could hardly be maintained that we are able to have, now, an experience of ‘dependence’ on a long-ago act of initial creation.) It could still be said that we are ‘dependent’ on God in the sense that he could annihilate us at any moment - but that is precisely the sense in which hostages become dependent upon terrorists to spare their lives; it is hardly of much use to religion. To be sure, it may be that none of these arguments would have persuaded the deists, who seem to have felt that although religion is somehow necessary, the course of prudence is to get along with as little of it as one can manage.

6 Contemporary issues

For most of the nineteenth and twentieth centuries, such metaphysical reflections as these were out of fashion, and various other issues came to the fore. A problem of some importance in the mid twentieth century was the question of the meaningfulness and intelligibility of the doctrine of creation. It was noted quite correctly that, once we get beyond crude anthropomorphic ideas of ‘making’, the terms used in speaking of creation are employed in ways far removed from their familiar uses. The question, then, is whether the ordinary meaning of the terms has not been eroded away without remainder, and without anything else having been put in its place. There are indeed analogies that can be adduced here: our experience of the instability of many things (for example, of a home constructed in an earthquake zone) may illuminate the ‘ontological instability’ of things and thus their dependence upon God. And we speak of God as ‘planning’ for the world by analogy with our own planning for future contingencies. But the instabilities we are aware of are instabilities *within the world*, remediable by ordinary, intra-worldly means;

our experience of planning presupposes all sorts of limitations on our part which are explicitly excluded in the case of God. So the meaning which our analogies seem to provide may well prove to be illusory.

It is fair to say that this sort of objection became progressively less compelling during the second half of the twentieth century. To speak about the doctrine of creation with some accuracy it is indeed necessary to speak in explicitly metaphysical terms - something which philosophers have increasingly found themselves willing and able to do (for example, Richard Swinburne and Alvin Plantinga). The analogies with ordinary experience are undoubtedly important in enabling us to grasp the significance of the doctrine. But the analogies are abused if we demand that the very same relation which obtains between God and creatures should be exemplified in the relations between creatures.

Most contemporary discussion of creation concerns its relation to natural science. Much of this discussion is over points in contention between the worldviews of theism and scientific naturalism, and cannot be considered here. But there are two points at which science impinges directly on traditional thinking about creation: evolutionary biology, and cosmology.

There is a broad consensus among theologians, including most conservative theologians, that biological evolution as such poses no threat to the doctrine of creation. There is, however, a need to contest philosophical interpretations of evolution in terms of scientific naturalism, interpretations which are sometimes propounded by leading scientists. There is also a need to rethink certain areas of theology (especially theological anthropology) in the light of the acceptance of human evolution. There are differences among theologians over the extent to which evolution should be incorporated into positive theological teaching. Neo-orthodox theologians such as Karl Barth and Emil Brunner accepted evolution, but it was peripheral to their major theological concerns. Teilhard de Chardin, on the other hand, sought to establish a strong positive relationship between Christian hope and evolutionary optimism.

An area of particular interest is the relationship between the doctrine of creation and scientific cosmology (see God, arguments for the existence of §5; Religion and science §6). Here theology seems to be in the unusual position that it cannot be harmed by science but might be in a position to benefit from it. The key theological point at issue is the age of the universe as finite or infinite. It seems theology has nothing to fear from cosmology on this point. There is for one thing the possibility (though not a favoured possibility) for theology to accept an eternal universe (see §4 above). On the other hand, it seems that it would not be possible for science to establish that the universe is infinitely old: what might a scientific proof of that look like? If science were to find no evidence for a ‘beginning’, then at worst theology would be back in the same position as that accepted by Aquinas - able to say that reason cannot settle the issue, but that revelation informs us of a temporal creation. In fact, however, the triumph of ‘Big Bang’ cosmology over the ‘steady state’ theory (with additional help from the second law of thermodynamics) seems to provide substantial support for the idea of a temporal origin of the universe. It would be unwise for theists to cite these scientific developments as ‘proof’ of an absolute beginning, and thus of the need for a First Cause. Such a claim would underestimate the ingenuity of scientists, who continue to produce scenarios which permit an eternal universe. (To be sure, the scenarios available at present are highly speculative, and some of them may be motivated as much by aversion to the idea of an absolute beginning, and therefore a possible creation, as by empirical data.) But one may at least conclude, with Ernan McMullin, that ‘if the universe began in time through the act of a Creator, from our vantage point it would look something like the Big Bang that cosmologists are now talking about’ (1981: 39).

Crescas, Hasdai (*c*.1340-1410)

During the most tragic period of Spanish-Jewish history (1391-1492), Hasdai Crescas wrote a philosophical-theological treatise, Or Adonai (Light of the Lord), seeking to define and fortify the Jewish faith in the face of constant Christian attack. It is a polemical book, aiming to defend a traditional version of Judaism by criticizing the Aristotelian formulations proposed by such Jewish philosophers as Moses Maimonides and Levi ben Gershom (Gersonides). Since they relied on Aristotelian physics, Crescas began his reconstruction of Jewish theology with a demolition of Aristotle's natural philosophy. He then turned to metaphysics in general and Jewish theology in particular. His constructive work was especially novel in its treatment of human choice, divine omniscience and creation. Aiming to defend traditional Jewish ideas, Crescas in the end broached some of the most radical challenges to be found within the medieval philosophical tradition, including the proposal that there might be numerous worlds other than our own, infinite magnitudes, and a void, or vacuum.

1 Crescas' motives

Perhaps the most original and acute of all medieval Jewish philosophers, Hasdai Crescas lived through one of the most difficult periods of Jewish history. From 1391 to 1492, Spanish Jewry, the traditional repository of Jewish philosophy, suffered one defeat after another, culminating in the expulsion of the Jews who remained loyal to their faith in 1492. As chief rabbi of Aragonese Jewry, Crescas was continually called upon to defend both Jews and Judaism against the onslaughts of the Spanish clergy and populace. It is in this context that one must understand the purpose, tone and content of his major work, *Or Adonai* (1410), and his polemical tract, *Bittul 'Iqqarei ha-Notzrim (Refutation of Christian Principles)* (1398). The former work is the focus of our attention here, but it is noteworthy that the latter employs philosophical arguments throughout. One of its main theses is that core Christian dogmas are incompatible with reason.

One of the main threats to Judaism, Crescas believed, was internal: an 'alien woman', namely Aristotelian philosophy, had seduced Jewish thinkers and their followers into a misguided conception of Judaism, which made it easy for the Christians to convert Jews. To defend the Judaism he deemed authentic, Crescas proposed to banish the foreign influence by exposing its pretensions and demolishing its foundations. To this end, he was bold enough to focus his attack on the chief conveyer of the Aristotelian philosophy that had been imported into the sacred domain of the Torah, Moses Maimonides, whose Jewish creed was rooted in the conceptual framework of Aristotelian natural philosophy and metaphysics. *Or Adonai* constructs a new creed on very different conceptual foundations. In elaborating his views, Crescas is concerned to show that the authentic Jewish position is not to be formulated in or defended by Aristotelian language or arguments. Nevertheless, his method is philosophical throughout: to refute the Aristotelians he employs rigorous argumentation and fine analysis worthy of the best of his adversaries.

The credal structure of Judaism, Crescas claimed, is a fourfold system whose foundational axioms are the 'root beliefs' in the existence, unity and incorporeality of God. These three doctrines define religion generically, but only minimally. A higher tier is constituted by the ideas that make up a revealed religion, such as divine omniscience and prophecy. On the 'third floor' are the beliefs taught by the religion Crescas takes to be the true revealed religion - Judaism. These include the creation of the world, the primacy of Mosaic prophecy, and the coming of the messiah. Acceptance of these doctrines is obligatory for all Jews, but their truth is not entailed in the general concept of a revealed religion. Finally, in the 'attic' are views upheld by various Jewish sages which have no binding force, although one may believe in them. Examples include the plurality of universes, the existence of demons, and theories about the nature of the First Mover.

2 Critique of Aristotle

For the Aristotelian philosopher or theologian, metaphysics in general and theology in particular rest on natural philosophy. Thus Crescas' reconstruction of Jewish theology begins with a radical critique of Aristotelian physics. Maimonides had prefaced his exposition of the arguments of the Aristotelian school for the existence, unity and incorporeality of God by laying down twenty-six principles of Aristotelian natural philosophy. Although Maimonides himself had parted company with the Aristotelian tradition, he had explicitly criticized in detail only one of the Aristotelian philosophers' first premises that he listed, the eternity of the cosmos, treating the rest, by

and large, as useful cosmological axioms. Crescas targets the premises of the Aristotelian philosophers at large, aiming, through them, at what he conceives as unreasonable and damaging admissions of Aristotelian views by Maimonides.

The theological thrust of Crescas' 'scientific innovations' can be seen in his critique of several of the standard medieval proofs for the existence of God. Many of these arguments presuppose the impossibility of an actual infinity, an impossibility that Aristotle believed he had proved. There were arguments, for example, which assumed that there cannot be an infinite series of moving causes, so that there must be an Unmoved Mover as the ultimate cause of motion. Or, it was assumed, there cannot be an infinite series of causes and effects existing simultaneously, so there must be a First Cause to produce and sustain the whole series.

But why, Crescas asks, can there not be an actual infinity? After exposing flaws in Aristotle's arguments, Crescas affirms not only the possibility of an actual infinity but its existence. Space, he argues, the vacuum, is actually infinite. Here Crescas compounds his critique by identifying the void as infinite. For Aristotle had denied not only the possibility of an actual infinite, but also the possibility of a vacuum or void, which had seemed to him to involve a variety of absurd implications.

Aristotle and his followers had faced a vexing problem when asked what lies beyond their finite world. Aristotle's answer was that there is nothing - no vacuum, no space, no other world. In effect, he rejected even the question. To Crescas this seemed arbitrary at best. His own answer seemed more sensible: that there is infinite space beyond our world, extension, in which there is a real possibility of other worlds.

Having opened the door to the actual infinite, Crescas begins to open other doors as well: perhaps there is an infinite number of actual individuals or an infinitely large body. None of these hypotheses is absurd or improbable. Crescas' hospitality to an actual infinite was appreciated by Spinoza, who became a powerful advocate in behalf of an idea once widely taken by philosophers to be absurd on the face of it (see Spinoza, B. de §3).

3 Divine omniscience and human choice

The second part of Crescas' treatise discusses the theological dogmas presupposed by any revealed religion. His most penetrating discussions are found in his treatment of divine omniscience and human choice. He analyses these separately, but they can be discussed together since they are closely related in most medieval treatments. Like most medievals, Crescas defends a strong version of divine omniscience: God knows all truths. Many ancient and medieval thinkers had thought God's knowledge of future contingent facts problematic if not impossible. Gersonides (1288-1344), Crescas' 'philosophical litigant', had concluded that God does not know the future doings of human beings as individual events, but only the general laws pertaining to them. Crescas deems this not just false but heretical. After all, if God did not know Moses as an individual, how could God speak to him and give him the Torah? For Crescas, Gersonides' doctrine makes nonsense of the very idea of prophecy and revelation.

Crescas does not rest his case on revelation. He analyses each of Gersonides' arguments and finds them all invalid. He argues, for example, that even if it were true that temporal facts are known by temporal beings through sense-perception, it does not follow that this is the only way they are knowable. Why could a nontemporal being not know them in some nontemporal way? Since everyone agrees that God is eternal, it should also be admitted that God knows everything, including facts about the future, eternally, that is, timelessly. Strictly, there is no future or past to God. Crescas' solution is similar to that reached by many late ancient and medieval thinkers, such as Proclus, Boethius and Aquinas, but he was the first to propose it in the Jewish philosophical literature.

Now if God knows future contingents timelessly, can we still say that our choices are themselves contingent, or free? If not, all legal and moral obligations would be pointless. Crescas' response to this ancient dilemma, as he himself realized, is more novel and daring than his answer to the question about divine knowledge. He declares boldly that in one sense, in so far as they have causes, our choices and the actions based upon them are determined and necessary.

Crescas is an explicit and unabashed defender of causal determinism, not only in nature at large but in human behaviour specifically. If our choice to give charity were uncaused, it would be inexplicable and groundless. But should such an event be the subject of praise and reward? Crescas' answer is that, even though the event is

necessary in so far as it is caused, it is contingent as such, that is, considered in itself, for it is a logically possible state of affairs, not a necessary truth like the theorems of logic or mathematics. My act of charity has a cause, and in this sense is determined and necessary, but it is still free, since it is, in itself, merely a logically contingent state of affairs. As long as I am not subject to external compulsion, such that I feel forced, an action can be deemed voluntary. So what I do tomorrow remains contingent, despite God’s eternal knowledge. Indeed, in different circumstances I could have acted otherwise. And God, in that case, would eternally have known otherwise.

4 Creation

In Part Three of *Or Adonai*, Crescas discusses those beliefs that are not essential to all revealed religions but are taught by the one revealed religion that Crescas takes to be true, that of the Torah. He begins by discussing creation, which is the first belief explained in the Torah. By Crescas’ time, creation had become one of the most controversial issues in philosophy. Three theories were widely debated: (1) the eternalism of Aristotle and his followers; (2) the theory of *formatio mundi* attributed to Plato, creation understood as the formation of an orderly cosmos out of formless matter; and (3) the doctrine by now most generally regarded as orthodox among Jews, Christians and Muslims, *creatio ex nihilo* (see Creation and conservation, religious doctrine of; Eternity of the world, medieval views of).

Crescas focuses chiefly on Gersonides’ modified version of the second theory and Maimonides’ support of the third. He rejects his two predecessors’ rebuttals of Aristotle’s arguments in favour of eternity and against creation, finding them either invalid or dependent on theorems of Aristotelian physics which were shown in Part One of *Or Adonai* to be false or unproved. As in his treatment of divine omniscience, Crescas is especially incensed by Gersonides, whose defence of *formatio mundi* he believes to be a misreading of the Torah and demonstrably false. Gersonides had relied heavily on the claim that *ex nihilo* creation implies the existence of a vacuum before creation and its persistence outside the world even afterwards. But, as we have seen, Crescas is prepared to defend the possibility of a vacuum. Besides, Gersonides’ argument is unsound: in creating the universe God created its spatial dimensions along with it; no empty space was needed before creation.

After disposing of the arguments of Gersonides and Maimonides, Crescas presents his own solution, redefining *ex nihilo* creation to refer to the world’s causal dependence on God. No ‘prior’ matter is needed. Indeed, the whole formulation is temporally neutral: the universe could be eternal albeit created, that is, eternally dependent upon God. A similar view had been defended by the Muslim Neoplatonists al-Farabi and Avicenna (see Ibn Sina). Crescas understands that dependence on their approach might offend some of his readers, so he offers a weaker, more traditional version of the idea: instead of one eternally existing world, an infinite series of worlds might be created by God. Our world, in that case, did have a definite temporal beginning, as tradition teaches, but God’s creativity continues at all times. Both doctrines preserve the important dogma of divine omnipotence.

5 Plurality of worlds

The final part of Crescas’ treatise contains thirteen short disquisitions on various topics about which there is no unanimity among the sages, but where plausible arguments have been adduced in favour of diverse positions. Since these doctrines have no dogmatic status, a Jew is free to affirm or deny them, or to withhold judgment.

The first of these questions is whether this world could be destroyed and replaced. Is ours only one of a series of successive created universes? This was a question of considerable interest to Christian theologians in the fourteenth century. Few Jewish philosophers had devoted much discussion to the question, although there are hints of the idea in the Rabbinic literature, and Maimonides and Gersonides had defended the indestructibility of our universe. Crescas finds none of the arguments for or against a succession of worlds compelling. But his previous suggestion that God can create an infinite series of worlds shows his attraction to this view. It is quite possible, he says, that God could destroy this world and create a more perfect one. But if so, Crescas insists, God would destroy the earth only; the heavenly bodies are everlasting. It remains in doubt whether this last is consistent with Crescas’ views on eternal creation.

In the second question Crescas wonders whether there could be a plurality of coexisting worlds. Gersonides, following Aristotle, had defended the uniqueness of the cosmos: one God, one world. Crescas is not so sure. He seems to lean towards the view that other worlds might coexist with ours. Aristotle had urged (among other

arguments) that since each of the physical elements has a natural place towards which it moves if nothing impedes it (such as fire, which naturally moves upwards towards the outermost region of the earth) then if there were another world, fire *there* would move towards the outermost region in *our* world. Since this seems untenable, our world must contain all the matter there is, and no other universe is possible. Crescas rejects this argument. Even if the theory of natural places is true - and Crescas denies it - the fire in another world would move towards the outermost region of *that* world, not ours. The doctrine of natural places, if true, must be relativized.

There is a certain unintended irony in Crescas' enterprise. He set out to defend a traditional Jewish theology, purified of Aristotelian intrusions. Yet the conclusions he reaches are novel, sometimes radical. He rejects the Aristotelian cosmology that had served for centuries as the backdrop for medieval philosophical speculations. He redefines key theological ideas. Even his pupil, Joseph Albo, criticized and rejected Crescas' deterministic account of choice. And his ill-concealed sympathy for 'eternal creation' is hardly unanimously hailed among later thinkers. The (somewhat Epicurean sounding) proposals about an infinite void and multiple worlds fell largely upon deaf ears, until, in the aftermath of the modern discrediting of the medieval worldview, Crescas' ideas found a sympathetic reader in Spinoza.

Crime and punishment

An account of how state punishment can be justified requires an account of the state, as having the authority to punish, and of crime, as that which is punished. Crime, as socially proscribed wrongdoing, may be formally censured, and may lead to the payment of compensation to those injured by it - but why should it also attract the kind of 'hard-treatment' punishment which characterizes a system of criminal law? How should we decide which kinds of wrongdoing should count as crimes?

Consequentialists justify punishment by its beneficial effects, notably in preventing crime by deterring, reforming or incapacitating potential criminals. They face the objection that the wholehearted pursuit of such goals would lead to injustice - punishment of those who do not deserve it. Even if that objection is met by imposing non-consequentialist constraints on the system, they also face the objection that a consequentialist system fails to respect criminals as responsible moral agents.

Retributivists hold that punishment must be deserved if it is to be justified, and that the guilty (and only the guilty) deserve punishment. Positive retributivists hold that the guilty should be punished as they deserve, even if this will achieve no consequential good. Negative retributivists hold that only the guilty may be punished, but that they should be punished only if their punishment will be beneficial. The main objection to retributivism is that it fails to explain why the guilty deserve punishment.

Some retributivists have argued that the guilty deserve censure, and that punishment serves to communicate that censure. But why should we use 'hard treatment' such as imprisonment or fines to communicate censure? Does the hard treatment function as a consequentialist deterrent? Or could such punishments serve to reform or educate criminals, thus bringing them to repent their crimes and restoring their relationships with those they have wronged?

A theory of justified punishment must be related to our existing penal institutions. It must, in particular, have something to say about sentencing: about what kinds of punishment should be imposed, and about how sentencers should decide on the appropriate severity of punishment. A central issue concerns the role of the principle of proportionality: the demand that the severity of punishment should be proportionate to the seriousness of the crime.

But we must also ask whether our existing penal practices can be justified at all. We must face the abolitionists' argument that punishment should be abolished in favour of social practices which treat 'crimes' not as wrongdoings that must be punished, but as 'conflicts' which must be resolved by a reconciliatory rather than a punitive process.

1 Punishment, the state and the criminal law

Our focus is on punishment imposed by the state for breaches of the criminal law. Punishment can be initially defined as the deliberate infliction of something meant to be burdensome, by an authority, on an alleged offender, for an alleged offence. It needs justification because it involves doing things (depriving people of life, liberty or money) which are normally wrong. Different moral perspectives, however, generate different accounts of why punishment is morally problematic and thus of what could justify it. Is what matters the infliction of pain, for instance; or the apparent coercive infringement of rights which punishment involves?

A justification of state punishment presupposes a normative theory of the state, as having the authority to punish. Different theories of the state generate different conceptions of punishment: a liberal theory, for example, might set more modest aims for state punishment, and subject it to stricter constraints, than would a communitarian theory (see Liberalism §5; Community and communitarianism §§2, 3).

A justification of punishment also requires an account of crime, since it is crimes that are punished. Crime can be minimally defined as socially proscribed wrongdoing, breaching an authoritative social norm (see Social norms). We require an account of the proper character and scope of such norms (and of what it is to be responsible for breaching them, since crime involves a criminal who can be held responsible for it) (see Responsibility §1). But not all breaches of socially (or legally) authoritative norms count as crimes which merit punishment: we must ask

what kinds of response are appropriate to different kinds of wrongdoing.

Censure is one proper response to breaches of authoritative norms, and the expression of censure may be a further defining feature of punishment; this distinguishes fines, for instance, from taxes (see §3). But censure can be expressed by formal declarations, or by symbolic punishments which are painful only in virtue of their expressive meaning, whereas criminal punishments typically inflict ‘hard treatment’ (the loss of liberty, money or life) which is painful independently of its expressive meaning. Why should such hard treatment be an appropriate response to socially proscribed wrongdoing?

Another response to such wrongdoing is the enforced payment of compensation to those harmed by it; this is a central feature of the civil as distinct from the criminal law. But though punishment may involve the payment of compensation, it also inflicts hard treatment that is not directly compensatory (nor do crimes always harm identifiable victims). Why should such punitive hard treatment ever be appropriate, and for what kinds of conduct? Which should count as crimes, rather than merely as civil wrongs?

Some theorists appeal to the ‘harm principle’ (see Law and morality §2): only conduct which harms or endangers others should be criminal. But this provides at most a necessary, not a sufficient, condition for criminalization: not every kind of (even seriously) harmful conduct is a plausible candidate for criminalization. And, apart from the question of whether paternalistic laws, prohibiting conduct that harms only the agent, can ever be justified, we must ask what counts as ‘harm’. Can we distinguish harmful from merely offensive conduct? Might we count some conduct as ‘harmful’ purely because of its moral character (as, for example, a breach of trust or a denial of rights) rather than because of its material effects?

Whether we talk of conduct that harms interests, or that infringes rights, or that flouts community values, we must ask which interests, rights or values should be protected by the criminal rather than the civil law. Crimes are often said to be public, rather than private or individual, wrongs: wrongs not just against some individual who may then claim damages, but against the community or state. That is why while civil cases are brought (and may be dropped) by individual plaintiffs, criminal cases are brought by the state or community, even when they involve an attack on an individual victim. But can we explain crimes as public wrongs, without distorting the way in which many crimes attack individual victims? To say, for instance, that murder and rape should be crimes not because of what they do to their particular victims, but because they threaten public order, seems to deny the significance of the victim’s suffering. We might suggest that even crimes against individual victims should count as ‘public’ wrongs in that the community should identify itself with the victim, counting the victim’s wrong as ‘ours’. Or we might abandon the idea of crimes as public wrongs (except for those which directly injure the collective rather than any individual, like tax evasion), and portray crimes as attacks on those central rights or interests which the state should protect. Either approach, however, leaves us with the question of which rights or interests should be thus protected, or which wrongs should thus be seen as public wrongs. Or if we say that the criminal law should protect the values which are essential to the identity or existence of the community, we must ask which those values are. (Any account of crime must also explain the distinction between *mala in se*, acts which are wrong independently of any legal rule, and *mala prohibita*, acts which are wrong only because prohibited. *Mala prohibita*, however, include many offences (notably ‘regulatory’ offences, such as minor traffic violations) which some think should not count as true ‘crimes’: they should be dealt with, not by a criminal process which censures and punishes, but by some distinct regulatory procedure.)

Instead of asking directly which kinds of conduct should be criminalized, we might ask what justifies criminal punishment, and found our principles of criminalization on our answer to that question. If the central justifying aim of punishment is deterrence, we can ask which kinds of conduct should be thus deterred; if its proper aim is ‘retribution’, we can ask which kinds of conduct merit such a retributive response.

2 Consequentialism and retributivism

Penal theory has long been a battleground between consequentialists and retributivists. After a period of consequentialist domination, the 1970s saw a revival in retributivist thought, as part of a wider rights-based reaction against consequentialism in social policy.

Consequentialists justify punishment by its instrumental contribution to certain goods: most obviously, the good of crime-prevention. A penal system is justified if its crime-preventive and other benefits outweigh its costs, and no

alternative practice could achieve such goods more cost-effectively. Punishment prevents crime by deterring, incapacitating or reforming potential offenders: by giving them prudential disincentives to crime, by subjecting them to restraints which make it harder for them to break the law, or by so modifying their attitudes that they will obey the law willingly (see Bentham, J. §3; Consequentialism).

It is at most a contingent truth that such effects on potential offenders are efficiently achieved by punishing actual offenders. This generates the familiar objection to any purely consequentialist theory, that it sanctions injustice. A system of deterrent punishment must appear to punish actual offenders: but that leaves open the possibility of framing innocent scapegoats to deter others or to reassure the public. And unless actual offending is the only reliable predictor of the future crimes which reformative or incapacitative measures aim to prevent, such measures might be efficiently (but surely unjustly) inflicted on those who have not yet broken the law but are thought likely to do so. Indeed, since a person's subjection to coercive treatment by the state must depend on the predicted effects of such treatment, rather than on their past conduct, we might wonder whether consequentialists can justify a system of punishment, of measures imposed for a crime, at all.

Some consequentialists do argue that we should replace punishment by other, more efficient methods of dealing with socially dangerous people. Others argue that we should accept the 'injustices' that a strictly consequentialist penal system might perpetrate (noting that we already accept, for instance, the pre-emptive detention of the mentally disordered). Most accept, however, that a justified system of punishment cannot perpetrate the kinds of gross injustice noted above.

Consequentialists might meet this objection by providing a fuller account of the goods to be achieved or protected, and of the methods by which they might practicably be achieved. Thus some argue that individual freedom is an essential good, whose protection precludes the deliberate punishment of those who have not voluntarily broken the law. Others argue that, given the fallibility of human agents, the only safe way to pursue the appropriate goods is to set strict constraints on the penal system: for instance, strictly to forbid the deliberate punishment of an innocent. Such consequentialist defences, however, depend on large empirical claims about the likely effects of penal strategies, which cannot easily be verified. Can the demands of justice to which this objection appeals really be adequately grounded in the contingencies on which this consequentialist argument depends?

Another strategy is to abandon pure consequentialism, and impose non-consequentialist side-constraints of justice on our pursuit of the consequentialist's goals: to insist, for instance, that only those who have voluntarily broken the law may be punished, since responsible agents have a right not to be subjected to such coercive measures unless they voluntarily make themselves liable to them.

One objection to even a side-constrained consequentialist theory concerns the moral standing of those who are punished or threatened with punishment: that a consequentialist system fails to respect its citizens (criminals and non-criminals) as responsible agents. A system of deterrent punishments, Hegel argued, treats all those whom it threatens with punishment like 'dogs': rather than seeking their allegiance to the law by appeal to the moral reasons which justify its demands, it coerces their obedience by threats (see Hegel, G.W.F. §8). A consequentialist system of reform similarly treats those subjected to it as objects to be remoulded, rather than as responsible agents who must determine their own conduct.

Against such objections, some argue that a side-constrained system of deterrent punishments can respect the moral standing of those it threatens and punishes; or that 'rehabilitation' and 'reform' need not be improperly manipulative or coercive. But one stimulus to the retributivist revival in the 1970s was the claim that only retributivism respects the moral standing of criminals: their right to receive 'fair and certain punishment', rather than being 'used merely as means' to the deterrence of others, or being subjected to indefinite terms of reformative 'treatment'.

The central retributivist slogan is that (only) the guilty deserve punishment, and deserve punishments proportionate to the seriousness of their crimes. This demand for 'just deserts' may be interpreted negatively, as forbidding the punishment of the innocent (or the excessive punishment of the guilty); or positively, as requiring that the guilty be punished as they deserve. The negative reading makes guilt a necessary, but not sufficient, condition of justified punishment: it suggests a 'mixed' account, which gives punishment a consequentialist aim but subjects our pursuit of that aim to retributivist side-constraints, requiring that punishment be both deserved and

consequentially beneficial. The positive reading makes guilt a necessary and sufficient condition of justified punishment: the guilty should be punished because they deserve it, whether or not their punishment achieves any consequential good (see Kant, I. §10).

The central task for any retributivist is to explain this supposed justificatory relation between guilt and punishment: what is it about crime that makes punishment an appropriate response to it? The central objection to all retributivist theories is that they fail to discharge this task: they either fail to explain this notion of penal desert, falling back on unexplained intuition or metaphysical mystery-mongering, or offer covertly consequentialist explanations.

The 'new retributivism' of the 1970s offered various accounts of the idea of penal desert. One was that criminals gained by their crimes an unfair advantage over the law-abiding, since they accepted the benefits of the law-abiding self-restraint of others, but evaded that burden of self-restraint themselves: their punishment removed that unfair advantage, thus restoring the fair balance of benefits and burdens which the law should preserve. One objection to this account is that it distorts the nature of crime: what makes rape punishable as a crime is surely the wrong done to its victim, not the unfair advantage the rapist supposedly takes over all those who obey the law.

Another trend in recent retributivist thought has rather built on the idea of punishment as an expressive or communicative practice.

3 Punishment and communication

Expressive accounts of punishment need not be retributivist: since by expressing censure we can modify wrongdoers' conduct, consequentialists can advocate expressive punishments. But the expressive or communicative aspect of punishment can explain the retributivist's slogan that the guilty deserve punishment: if they have broken a law which justifiably claimed their obedience, they deserve censure; and it is a proper task for the state, speaking on behalf of the community, to communicate that censure to them.

We should talk of communication rather than of expression here. For communication is a process which addresses (as expression need not) another as a rational agent; it captures the idea (central to recent versions of retributivism), that we must address criminals as rational and responsible agents.

But even if criminal wrongdoers should be censured, and hard-treatment punishments of the sort imposed by our penal systems can communicate that censure, we must ask why it should be communicated in this way, rather than by formal declarations or purely symbolic punishments (see §1).

Some suggest that hard treatment is necessary if the censure which wrongdoing merits is to be communicated effectively to the criminal, who might not attend to merely symbolic punishments; or that it may be necessary to 'defeat' the claim to superiority which was implicit in the wrongdoer's crime (but do all crimes make such a claim?). But why, if not for the consequentialist reason that this will make the punishment a more effective deterrent, is effective communication so crucial that we must inflict hard-treatment punishments to achieve it?

Others accept that a communicative retributivism cannot by itself justify the use of hard treatment as the communicative vehicle: it must be justified by a consequentialist concern for deterrence. This need not be the kind of 'mixed' account which portrays retributivist values merely as side-constraints on the consequentialist ends which give the penal system its positive aim. The communication of censure can itself be the central justifying aim of punishment, so that the law addresses the citizen as a responsible moral agent, appealing to the moral reasons which justify its demands and the censure that it imposes on those who flout those demands. But recognizing that, as fallible human beings, we will not always be adequately motivated by such moral reasons for obeying the law, we communicate that censure through hard treatment in order to provide an additional prudential incentive for obedience. On one version of this account, the hard treatment should provide only a modest prudential supplement which does not replace or drown the law's moral voice: the question then is whether such modest supplements will be effective. On another version, the hard treatment may be harsh enough to provide by itself an effective deterrent; but this will revive the objections noted earlier to a deterrent conception of punishment.

More ambitiously communicative accounts of punishment portray the hard treatment as a mode of moral communication which aims to reform or educate. Punishment aims to bring wrongdoers to understand and to repent their crimes, and thus to reform their future conduct. Hard treatment assists this purpose by helping to bring

home to them the meaning and implications of what they have done; it can also, if it is willingly undergone, enable them to express their repentance and thus reconcile themselves with their victims and the community. Such accounts are retributivist, since punishment must be focused on the past crime as an appropriate censuring response to it, but they also give punishment a forward-looking purpose: the offender's reform or rehabilitation, the restoration of the relationships which the crime damaged, the making of symbolic (and perhaps material) reparation to the victim and the community. Such purposes, however, are not to be understood in strictly consequentialist terms, as independent ends to which punishment is a contingent means: they can be achieved only through a punitive process which aims to persuade wrongdoers that they must suffer punishment for what they have done.

We must ask, however, whether hard-treatment punishment could ever be an appropriate vehicle for such a communicative, reformative and penitential endeavour; and whether, even if it could (as it might be in, for instance, a religious community that practises penance), the state should take such a coercive interest in the moral condition of its citizens. This conception of punishment might be at home within a communitarian perspective according to which individuals can find their identity and their good only as members of a community united by shared values and mutual concerns; but it seems incompatible with a liberal insistence on the need to protect individual rights and privacy against intrusive state or community power. Liberals can argue that punishment's primary purpose should be the communication of appropriate censure, but may deny that the state should try, by such coercive means, to secure repentance and reform; in which case hard-treatment punishments could be justified only as prudential deterrents which do not seek to invade the criminal's soul.

4 Penal theory and sentencing

Philosophical discussions of punishment are typically conducted at a level of high abstraction, remote both from the actualities of penal practices and from the pressing concerns of penal practitioners. But we must try to relate them to the real penal world.

One central issue is that of sentencing. What kinds of punishment should be available to the courts (capital punishment; imprisonment; fines; community service; probation)? What makes a particular kind of punishment appropriate, either generally or for a particular crime? How should sentencers determine the severity of punishment to be imposed on particular crimes or criminals?

Discussion of the last question often focuses on the principle of proportionality: the severity of punishment should be proportionate to the seriousness of the crime. Some such principle is integral to any retributivist theory, including communicative theories: for if punishment is to communicate an appropriate degree of censure, its severity must be proportionate to the seriousness of the crime. The application of such a principle requires some way of assessing and comparing the seriousness of different crimes, and the severity of different punishments; and it is not clear either just how, or how precisely, this can be done. Furthermore, while such a principle can help to determine the relative severity of sentences, requiring that more serious crimes be punished more severely, and so on, it is not clear whether it can help to fix absolute levels of punishment.

How important is the principle of proportionality? On some views, it is paramount: the primary aim of sentencing is to do justice by assigning proportionate sentences. This means, in practice, that the available range of punishments must be limited, and that the courts should have only very limited discretion in sentencing. Others argue that the demand for proportionality must be weighed against other relevant principles, such as a principle of penal parsimony which requires courts to impose the lightest acceptable sentence, even if that is lighter than is required for strict proportionality; on this view proportionality might be seen as a limiting principle requiring that criminals be punished no more severely than is proportionate to their crimes.

There is also a tension between the demand for proportionality and any ambitious account of punishment as communication. If punishment is given an educative, reformative or penitential aim, courts should seek punishments which are materially appropriate, rather than just formally proportionate, to the crime and the criminal: punishments which will appropriately address the particular criminal. But this would require the courts to be given a more flexible and creative discretion in sentencing, to find or construct sentences appropriate to the particular case: a discretion which might undermine demands for strict and formal proportionality.

Here again we face a conflict between a liberal perspective which emphasizes the demands of formal justice, and

seeks to protect the citizen against the coercive and discretionary power of the state; and a more ambitious conception of the proper role of the state and the criminal law in seeking the moral good of the citizens.

5 Can punishment be justified?

Any plausible normative theory of punishment will show our existing penal institutions to be radically imperfect. The kind and degree of suffering that they inflict cannot be plausibly portrayed as either consequentially cost-effective or retributively just, or well-suited to the aims of a communicative theory of punishment. Nor is it clear that the preconditions of justified punishment are satisfied in our own societies, especially if punishment is portrayed in retributive or communicative terms: can we truly say that most of those who are convicted by our courts have culpably flouted laws which justifiably claimed their allegiance, or that we (in whose name the law speaks) have the moral standing to censure them?

The radical imperfection of our existing penal institutions raises a serious question for any citizen. Should we accept those existing institutions (while also striving for their reform) as necessary to the prevention of yet greater disorder or injustice; or may we have to recognize that they perpetrate such serious injustice, or cause so much harm, that they cannot be justified at all?

The suggestion that, even if a practice of state punishment could in principle be justified, our existing penal institutions may lack any adequate justification, might seem frivolous: can we honestly argue that they should be abolished? But this is just what is argued by ‘abolitionists’, many of whom indeed argue that punishment cannot even in principle be justified: we should work not for the reform of our penal institutions, but for their abolition. Such arguments are not often considered in the philosophical literature, which tends to assume that the key issue is not whether, but how, state punishment can be justified; but they present a challenge that must be taken seriously.

Various themes run through abolitionist writings. One concerns the very concept of ‘crime’ as that which merits a punitive response: we should reconceptualize crimes as ‘conflicts’ that require resolution rather than punishment. Relatedly, we should ‘civilize’ our response to crime, favouring a civil law rather than a criminal model: rather than seeking ‘retributive’ justice by condemning and punishing those judged to have done wrong, we should seek ‘restorative’ justice by striving to reconcile the conflicting parties and (where necessary) negotiating reparation for whatever harm has been done. These themes are often accompanied by an advocacy of ‘informal justice’: rather than allowing the state to ‘steal’ conflicts from the individuals and local communities to whom they properly belong, we should look for informal, participatory modes of conflict-resolution. But punishment (the deliberate infliction of suffering) is never justified: neither as retribution (which is not a proper aim), nor as deterrence (which denies the moral standing of those who are threatened and punished). And while rehabilitative facilities may be offered to those who need and seek them, they can never properly be imposed on citizens.

Against such views it may be argued that some ‘conflicts’ involve the commission of genuine wrongs which should be condemned; that any morally acceptable ‘reconciliation’ must involve the recognition and acceptance of guilt by the wrongdoer (these considerations argue in favour of a communicative conception of punishment as censure); and that a society which truly forswore the whole coercive apparatus of criminal justice would be unable to protect itself or its members against seriously destructive wrongs and social disorder. We might imagine a more perfect society in which the kinds of hard-treatment punishment currently imposed would be unjustified, because unnecessary. We may agree that we now punish too much, too harshly, that our penal institutions do not serve the ends that punishment should serve, and that too often they inflict further suffering on those who are already seriously disadvantaged by the political and economic structures from which many of us benefit. Abolitionists forcibly remind us of these points; but this is not to agree that punishment can never be justified.

Criteria

The concept of criteria has been interpreted as the central notion in the later Wittgenstein's account of how language functions, in contrast to the realist semantics of the Tractatus. According to this later account, a concept possesses a sense in so far as there are conditions that constitute non-inductive evidence for its application in a particular case. This condition on a concept's possessing a sense has been thought to enable Wittgenstein to refute both solipsism and scepticism about other minds. There are powerful objections to this conception of criteria, which have led some philosophers to look for an alternative account of the role of criteria in Wittgenstein's later philosophy.

1 Criteria and scepticism

Norman Malcolm (1963) sets out the central argument by means of which Wittgenstein allegedly refutes solipsism and scepticism about other minds. Wittgenstein is held to expose the incoherence of the argument from analogy, and thereby to show that if we make the assumption that we know, for example, what pain is only from our own case, then we could never transfer the idea to others. This allegedly forces the defender of the view that 'pain' refers to a private object within a psychological realm into endorsing solipsism. Wittgenstein is then held to use the private language argument to show that solipsism is incoherent (see Wittgenstein, L. §13; Private language argument).

The solipsist has a concept of pain only if it makes sense to talk of identifying a sensation as a sensation of pain correctly or incorrectly. But what does it mean to say that the solipsist has correctly identified a given sensation as one of pain? The solipsist has neither a standard, a sample nor a customary practice of using the word 'pain' against which the inclination to apply the concept can be judged. There is nothing independent of this inclination that enables the solipsist to determine whether the application is correct or incorrect. But in so far as there is nothing to determine whether the application is correct or incorrect, the idea of using the word correctly or incorrectly makes no sense. And in so far as the solipsist lacks a criterion of correct application, the solipsist lacks a concept of pain.

Thus, the assumption that one knows what pain is only from one's own case is shown to lead to a contradiction: if we know about sensations only from our own case, then we cannot know about them even in our own case. It follows, Malcolm argues, that it is a condition of our being able to attribute sensations to ourselves that there should exist *criteria* on the basis of which we are necessarily justified in ascribing them to others. When these criteria are fulfilled, speakers do not merely have good inductive evidence that another is in pain (as the argument from analogy holds); they possess evidence that *establishes beyond question* that another is in pain.

This initially powerful rebuttal of scepticism is weakened, however, when Malcolm is forced to concede that there is a wide range of circumstances (being in a play, being hypnotized, pretending and so on) in which behaviour that would, in other circumstances, constitute criterial evidence for another's being in pain, does not count as fulfilling the criteria. Thus, what looks initially like an argument that establishes that there must be logically necessary and sufficient conditions for another's being in pain - that is, that there must be circumstances in which the behavioural evidence would make it a contradiction for the sceptic to deny that another is in pain - receives a fatal qualification. For given that a doubt may arise over whether the circumstances are ones in which criteria are satisfied (or really satisfied), it seems that the sceptic could always raise a question about any particular case. What looked like an argument to establish that our belief in another's pain is, on particular occasions, logically justified, is now reduced to the much weaker claim that there must be circumstances in which a speaker *accepts* that the criteria for another's being in pain are fulfilled.

There are a number of familiar objections to the argument that Malcolm attributes to Wittgenstein. First of all, it has been seen as amounting to little more than a version of verificationism, and as such it is thought not to warrant the status or the degree of significance that Malcolm ascribes to it. Secondly, it has been objected that the promise to provide a refutation of scepticism is undermined by the qualifications set out in the previous paragraph. It looked as if criteria were to enable us to show that our belief in another's pain is logically justified, but it turns out that the satisfaction of criteria on particular occasions is something that we must ultimately just accept, even though a doubt is, in some sense, still possible. The sceptic could be forgiven for regarding this as vindication,

rather than refutation, for there remains a gap between evidence and truth that must be filled by brute faith that our criteria are satisfied. At this point we seem justified in returning to Wittgenstein's texts to see if there is an alternative interpretation of his use of the concept of criteria.

2 Criteria and grammar

The principal concerns of Wittgenstein's later philosophy are the false pictures of language and of psychological phenomena that plague us in philosophy. These myths and false pictures arise, Wittgenstein believes, when we treat the phenomena that characterize our human form of life - language, consciousness, thought, action and so on - as things whose essence lies hidden from us. We both discover the emptiness of the pictures we construct, and achieve the understanding that we seek, through what Wittgenstein calls a 'grammatical investigation'. His idea of a grammatical investigation is characteristically rich. He describes such an investigation as one in which 'we remind ourselves of the kind of statement that we make about phenomena'. Because the essence of language and psychological phenomena lies open to view in the forms of our ordinary practice, it is through a careful description of our actual employment of expressions that we come to understand the nature of these phenomena. The understanding which a grammatical investigation achieves simply sets before us 'what already lies open to view', but in such a way that it no longer puzzles us or cries out for further explanation. Part of the difficulty in understanding Wittgenstein's later philosophy is that he does not believe that the understanding which a grammatical investigation achieves can be expressed in the form of a clear, unambiguous description of the structure and function of language in general, or of our psychological language game in particular.

It is possible to see Wittgenstein's concept of criteria not as a theoretical term of art but as linked in important ways with this idea of a grammatical investigation. Thus, asking for the criteria that ordinarily establish, in the sense of *identify*, something as an instance of a specific kind of thing (as a mistake, as expecting someone between 4.00 and 4.30, as understanding the order 'Add two' in the way that it was meant and so on) is one particular form of grammatical investigation. Other forms include asking how we teach someone a concept, asking how we would explain it, asking whether we would apply it in certain non-standard cases, asking whether certain facts being different would make it unusable, comparing it with a concept that Wittgenstein invents, and so on. Wittgenstein uses these forms of investigation to induce the clarified vision of the workings of our ordinary language games that he believes is essential to our coming to recognize that everything we need to understand language and psychological phenomena is already there before our eyes.

One of the principal lessons of the grammatical investigation of our ordinary criteria is that the criteria governing our concepts are much more complicated, our language games much more subtle and involved, than at first appears. In the case of psychological concepts this complexity is expressed, not only by the first-person-third-person asymmetry which characterizes these concepts (for example in the case of pain, I do not attribute pain to myself on the basis of observation, the concept of a mistake does not apply in the first-person case, and it makes no sense for me to doubt whether I am in pain), but also by an indeterminacy and uncertainty which Wittgenstein again takes to be a defining feature of our psychological language game. Wittgenstein believes that it is in part these grammatical features of our psychological concepts that prompts the philosopher to form a picture of the mental as an inner realm. For not only is the first-person-third-person asymmetry captured in the distinction between inner and outer, but the idea of the inner allows us to interpret the indeterminacy and uncertainty that is inherent in the language game as merely epistemic: the facts are there alright, but hidden beneath the surface that the other presents to the world.

Wittgenstein's grammatical investigation is directed at a complete overcoming of the philosophical myth of the inner. On the one hand, he tries to show that the picture of a determinate inner realm not only plays no role in our ordinary language game, but that it has no real application. His tactic here is not to try to refute the philosopher's claims, but to develop and explore them in such a way that we come to see, not only that no such thing is ever ordinarily in question, but that the picture of a private inner realm, which initially seems so clear to us, has no real content. He does not argue that no precise system of concepts linked, for example, with exact physiological readings of what is occurring in our brain and nervous system could never be constructed, but he tries to show us that such a system of concepts would not tell us what pain, or thought, or understanding really are; it would in no sense be a refinement of our system of psychological concepts, or constitute an explication of the phenomena that make up our form of life.

On the other hand, Wittgenstein's detailed exploration of the complex, infinitely nuanced language game that the process of acculturation initiates us into, gradually enables us to see how our language game actually functions, and to resist the temptation to misrepresent it in the myth of the inner. He works to overcome our sense that to abandon the idea of a private inner realm is to deny something vital, something without which we are mere machines. He uses the techniques of grammatical investigation to show that our philosophical picture of the inner is grounded in a fundamentally mistaken idea of the relation between our ordinary psychological concepts and the characteristic forms of movement, gesture and expression of the living bodies of humans and other animals. The division which we are mistakenly inclined to draw between an inner and outer realm is shown to be one that is actually grounded in the grammatical distinctions between psychological and non-psychological concepts.

Thus, we gradually come to see that our ordinary psychological language game is distinctive, not in that it describes a hidden realm of facts, but in its grammar. The grammar of our psychological language game reveals the nature of the facts it describes, and in recognizing the distinctiveness of this grammar, we recognize the distinctive form of the phenomena with which we are concerned. Thus, the first-person-third-person asymmetry which characterizes psychological concepts is not something that needs to be explained by (the empty) appeal to a special sort of fact (private facts); rather, this asymmetry itself reveals the distinctive form of mental phenomena.

Likewise, pretence, deceit, betrayal, as well as the ordinary dissemblings that constitute polite behaviour, are part of the form of our psychological language game, and not an unfortunate or incidental addition to it. These phenomena should not lead us to downgrade the 'outer evidence', but to recognize the subtlety and the complexity of the criteria we operate with. Sometimes we are sure of our judgment that another's feeling is genuine, sometimes anyone who is not a lunatic will share our certainty, but at other times we are uncertain and the judgment of different speakers may vary. What Wittgenstein tries to show is that this reflects the essential complexity and ambiguity of our criteria, and not the hiddenness of the facts; our uncertainty arises from the complexity and the subtlety of our relations with others and of the patterns that our psychological concepts require us to discern, and not from the indirectness of our evidence.

Wittgenstein's later philosophy of psychology clearly does constitute a concerted attack on the myth of the inner. This attack does not, however, take the form of a theory of how language functions that imposes on psychological concepts the requirement that what is inner is criterially linked with what is outer. The understanding of psychological phenomena that Wittgenstein's grammatical investigation offers is, in a sense, much more radical than this suggests. What we are gradually brought to see is that the nature of psychological phenomena is not hidden; that the evidence for their existence is not indirect, but involved and complex; that everything that we need to understand the essence of these phenomena is already there in the distinctive grammar of our language game, as this is revealed, for example, by the nature of the criteria with which we operate.

Critical Legal Studies

Critical Legal Studies first developed in the USA in the latter half of the 1970s. Drawing on the political inspiration of the contemporary New Left, it was an intellectual movement committed to radicalizing legal theory by bringing together US legal realism and modern European social theory. In so doing, it sought to provide a fundamental critique of the nature and place of law in modern capitalist society.

In its first phase, its main target was the liberal positivist theories of law that dominate Anglo-American jurisprudence. Such theories inform both the organization of the traditional legal curriculum and the nature of legal practice. By contrast, Critical Legal Studies saw law as based upon deeply contradictory premises, so that the orthodox positivist claim that law could be in principle rational and coherent was rejected in favour of the 'indeterminacy thesis'. Legal decisions were in truth a matter not of logical deduction but of choice. They could always go one way or the other. Ultimately, therefore, it was an open political decision made by a judge which determined a legal conclusion. The idea of the 'rule of law' operating above politics was rejected, but regarded as important in terms of the political legitimation function it served in Western societies.

While the name 'Critical Legal Studies' has a US provenance, a number of different critical legal projects can be identified. These projects reflect the broader character of the national traditions of which they are a part. European approaches, particularly the German and the British, reveal a more sustained engagement with modern and postmodern social theory. However, as a result of problems in the original project, Critical Legal Studies has entered into a second phase in the USA in which there is an increasing interest in social theory. The result has been a convergence of European and US concerns, but around a highly fragmented group of modern and postmodern social theories. Nietzsche, Foucault, Derrida and Habermas have been introduced into legal theory while Marx and Weber, the original theoretical mainstays of a critical approach to law, have been sidelined. There is a danger in this that Critical Legal Studies will become little more than a group of theorists talking among themselves. While the original US critique of legal doctrine may have run out of steam for want of sufficient theoretical sophistication, it is important not to lose sight of its direct focus on law and legal forms. It is arguable that the recent 'turn to theory' must validate itself in terms of the contribution it is able to make to a critical understanding of law and its practices; also that an important, as yet unaddressed, question concerns the relationship between postmodern forms of criticism and sociological analyses of the development of law.

1 Introduction

Critical Legal Studies as an approach to legal theory is a relatively recent phenomenon beginning in the second half of the 1970s and continuing to the present. It therefore comprises a body of thought that is hard to summarize or judge conclusively. Contributing to the problem is the variety of approaches within it, such that one can talk more easily of a 'movement' than a 'school' or a 'canon'. Notwithstanding the common New Left political heritage, the problem is further compounded by the existence of distinct Critical Legal Studies approaches in the USA and in a variety of west European countries, and by the dynamic, unstable and increasingly fragmentary character of their development. Critical Legal Studies in the early 1990s has a substantially different agenda and set of interests from that of a decade ago. In the light of these problems, it is proposed to begin with a picture of the trends of development in three different countries, the USA, Germany and Britain, before proceeding to offer a general assessment. With regard to this second objective, it is important to consider the relationship between Critical Legal Studies, legal studies in general, and broader movements in social theory. It is only in that context that a deeper perspective on the character, potential and limits of Critical Legal Studies can be achieved. A caveat must however be entered that in relation to so broad, disparate and currently evolving a movement, all generalizations and judgments are more than usually tentative.

2 Critical Legal Studies in the USA

A Critical Legal Studies movement first began in the late 1970s in the USA. The approach was characterized by the marriage of an existing legal realist tradition (see Legal realism §3) with a radical leftist antipathy to law which, while nominally committed to theoretical critique, was in general only weakly informed by an understanding of radical theoretical traditions. A recent survey of Critical Legal Studies (Boyle 1991) refers to the relevance of socialist, structuralist, deconstructionist, feminist, phenomenological and Hegelian theory. Critical

Legal Studies in the USA was always catholic in its sources, but never particularly deeply engaged with theory. It was more comfortable with a relatively narrow critique of the dominant legal tradition and its closer theoretical supports - economic analysis of law or a narrowly philosophical liberalism for example - than with a synthesis of the legal realist tradition and broader social theory (see Social theory and law §4). In recent times, the balance has been redressed through a deep interest in theory, but this has been accompanied by a move away from the earlier critiques of doctrinal analysis, in their time so powerful.

Critical Legal Studies in the USA directed itself against the dominant rationalist and formalist approach to legal studies. Legal realism had already introduced a sceptical critique of the possibility of coherence or consistency within a system of legal rules. Principles could always be opposed by counter-principles or by policies; rules were always subject to exceptions which threatened to swallow them up; the demand for fixed rules always existed in tension with broader standards which could be invoked against them; supposedly clear distinctions such as that between the private and the public were ultimately untenable. Realism's critique flowed from a dissatisfaction with formalistic and positivistic accounts of law (see Legal positivism §3), but its aim was pragmatic: to find a better way of comprehending law in order to put it to better use. Critical Legal Studies by contrast was informed by a more radical political standpoint that saw law not as an instrument to be used in the service of reform but as itself, in its very form, a barrier to social change. In its abstraction and pretence of rationality, law was essentially alienating and disempowering. The critique of law was therefore aimed at breaking the grip of traditional legal thinking upon the consciousness of lawyers and, in an unclearly defined way, 'the people' as a whole. In place of pragmatism, Critical Legal Studies substituted another peculiarly US intellectual current, populism.

A key concept (that was later to be repudiated) was that of a fundamental contradiction in a capitalist society - or, perhaps, all social life - between the individual and the social (Kennedy 1979). The conflict between self and others manifested itself in a variety of forms within law: in the clash of individualist and altruist principles, in the distinction between the private and the public (see Privacy), or between the subjective and the objective. Because this contradiction was fundamental, any attempt to reconcile its two sides was impossible, and legal rationalism was no more than a means of suppressing or hiding it. The existence of contradiction within law also explained the practical adversarial method of the lawyer, and illustrated the central contention of Critical Legal Studies that legal decision-making was essentially a matter of choice that could only be made according to political, as opposed to compelling internal, legal, criteria. The trick of the law was to make this political choice appear to be based upon apolitical rational grounds. The resulting 'legal consciousness' constituted the basis for legitimating forms of ideology in the broader society.

From this brief description, it will be seen that Critical Legal Studies contained a number of strands that did not necessarily add up to a coherent alternative perspective. That law and politics are intertwined is a claim that is not incompatible with more flexible varieties of legal positivism; nor is the argument about the fundamental contradiction within Western thought and law necessarily linked to it. With regard to the latter, it is important to know whether the contradiction is historical or existential. If it is a condition of all sociality or of an evolutionary modernity, then law will be regarded in a different light than if it is seen as a product of capitalist society with its own particular alienating forms. If the resulting legal consciousness is a significant mode of legitimation in the broader society, what are the mechanisms through which this occurs? The problem for Critical Legal Studies was that it remained unclear about the bigger questions that were necessarily inherent in its project. It could lead both to a call to the barricades and to a reconstructive legal project, both to a rejection of law in favour of a radical remaking of the world through informal communitarian modes of regulation and to a commitment to a revised liberal legalism (a 'super-liberalism' in R.M. Unger's 1986 account). It could also lead to individual nihilism, personal angst and intellectual incoherence as two hundred years of liberal legal thought was 'trashed' without much to put in its place.

In its earlier, stronger phase, Critical Legal Studies never moved from what Alan Hunt (1986) has called 'theory adoption' to 'theory construction'. It therefore found itself resting on insufficiently theorized premises that were hard to defend, and which left it vulnerable to counterattack. The 'fundamental contradiction' was eventually, somewhat cavalierly, renounced (Gabel and Kennedy 1984) while the precise scope of the 'indeterminacy thesis' has remained indeterminate. James Boyle (1991) has recently reflected upon the problems of transition from critical legal thought to social theory and of the eclectic quality of the former. Yet it is to be doubted whether his suggestion that Critical Legal Studies should be content with what he calls 'local theory' will assist it in reaching

beyond some of its impasses. This is not to deny the value of much recent work on law and culture, as well as critical race theory and feminist legal analysis (see Feminist jurisprudence), but the more specific direction of this often sophisticated critical work leaves broader issues necessarily unaddressed. The consequence has turned out to be a theoretical turn which frequently leads away from law and into an engagement with modern and postmodern trends in social theory. Compare in the area of feminist critique of law, for example, MacKinnon's (over-)direct analysis of the gendered character of law (1987) with the later, more sophisticated but abstract deconstructionist approach of Cornell (1991). As Goodrich (1993) comments, this route will ultimately be validated only if it leads to new and deeper understanding of law, as opposed to further, more *recherché*, repetitions and (mis)translations of Continental theory.

3 Critical Legal Studies in Germany and Britain

If US Critical Legal Studies in its first phase was reluctant to link theoretical analysis to the critique of legal formalism, the same cannot be said of the parallel German tradition. In Germany, *Politische Rechtstheorie*, the counterpart to Critical Legal Studies in the USA, coupled an interest in the critique of legal formalism with analysis based upon historical materialism, Enlightenment philosophy and post-Weberian sociology of law. Just as Critical Legal Studies drew upon the native critical tradition provided by US pragmatism, populism and legal realism, so German critical legal theory has drawn on the wider traditions of modern classical and post-classical European thought.

The major axes of German thought are provided by the Enlightenment commitment to a philosophical rationalization and legitimation of law, and by the Marxist materialist tradition. Modern debates within these two approaches are also substantially mediated by what might be called the 'Weberian problematic' which involves the post-classical conflict within specifically legal thought between formal and substantive justice. German critical legal thought in this regard has been much concerned with the problem of the 'materialization' of law in the twentieth century, and how legal theory between Hegel and Marx should orient itself to it.

Three primary routes can be identified. The first, fundamentally Marxist, route sought to derive forms of law and the state directly from the logic of capitalist economic development (Holloway and Picciotto 1978). Such an approach came to be regarded as ahistorical and aprioristic and fell into disfavour in the late 1970s, yet it retains a broad residual presence within critical legal thought. It is an approach that compares and contrasts with a second route developed in particular by Jürgen Habermas (§4), which seeks to understand law both as a 'control medium' for capitalism linked with strategic political and economic action, and as a universalistic form linked to the life world and rational communication (see Communicative rationality). In his earlier work on legitimation crises, Habermas (1976) used this emerging dualist perspective in order to analyse critically the social contradictions of law in the welfare state, but his more recent work reveals an endorsement of legal formalism, at the same time as it finds it difficult to recognize the concrete legal forms within which formalism could be instantiated (Habermas 1988). Habermas' work can be seen as an Enlightenment-inspired attempt to establish the possible legitimacy of legal institutions in a post-classical world that has rejected in theory and practice the possibility of a formal justice rooted in positive law.

A third route extends the biological conception of the 'autopoietic' (self-referential and self-sustaining) system to legal and other social systems. This theory responds to the multiple conflicts between formal and substantive law by embracing them and at the same time rejecting the role of law as legitimative. In this account of law, emphasis is placed upon the autonomous and self-reflexive character of law within a social system that is differentiated into heteronomous, self-operating sub-systems. These sub-systems are largely closed to each other, and operate according to their own languages and imperatives. They receive inputs from other sub-systems and provide outputs to them, but all such inputs and outputs must be translated into the language of the sub-system itself. Autopoiesis proposed a radical form of system closure, which has been used to explain the propensity to regulative failure built into legal systems, and to provide a critique of 'juridification' as a system-imperative of the legal sub-system. The problem for autopoietic theory is that, despite its critical rhetoric, it presents a view of law that is little different from that of the self-understanding of the lawyer. Its roots in biological metaphor and its aprioristic method lead it to a sociological view of law's functionality unrelated to social or historical development, teetering on the brink of solipsism. Autopoiesis has rejected the linkage between law and an immanent morality explored by Habermas and his associates, but it has not established a sufficiently critical purchase point from which to understand law. Its

view of law can in some respects be compared with that of Weber, for whom modern legal rationality was part of the 'iron cage' of bureaucracy which entrapped humankind, and from which there was little chance of escape (see Weber, M. §2). It might be said to reflect the proclaimed problems of modernity without possessing the critical resources to deal with them.

British Critical Legal Studies can be seen as characteristically resting somewhere between the USA and the German traditions. Compared to the latter, the British have largely been entrapped within an empirical and utilitarian intellectual tradition that has hardly encouraged a deep interest in or respect for the value of theoretical approaches to law. British Critical Legal Studies lack, the German adherence to a sense of 'schools of thought' or of the necessity of locating oneself within a particular theoretical tradition (other than the positivist, of course). While one should stress a common background in the Marxism of the 1970s, the British approach is now more eclectic, more inclined to draw according to interest or fashion from a variety of Continental theories. Compared to the USA, however, the British critical theorists reject the value of populist or pragmatic modes of thought, and are more deeply committed to theoretical engagement with law. By comparison, they benefit from a deeper engagement with theoretical traditions in the sociology of law which goes back to structuralist, form-derivational and feminist debates of the 1970s. The result has been that, in a comparatively small intellectual community with a common background, there has emerged a relative diversity of approaches of some depth to critical legal analysis.

While it is therefore difficult to speak of a British approach to Critical Legal Studies, a range of individual British critical approaches can be identified. To name three of the more recent authors, Peter Goodrich (1990) has drawn upon Nietzsche and Heidegger to establish a critical counter-aesthetics of law and judgment to weigh against English legal traditions; Peter Fitzpatrick (1992) has brought together a Derridean sense of myth and a critique of colonialism to establish what he describes as the mythical foundations of modern law; and Alan Norrie (1993) has combined form analysis, social history and critical realism to establish a praxiological account of criminal law and punishment. These works share themes, but their intellectual allegiances and methodologies - within the current critical canon - vary.

4 Theoretical overview

Critical Legal Studies in the USA, Germany and Britain are characterized by a wide range of intellectual sources which include elements of Marxism, deconstruction, legal realism and Neo-Kantianism (as in autopoietic theory), as well as attempts to recreate the Enlightenment project (such as that of Habermas). They have in common a political and intellectual desire to transcend the positivist and formalist tradition; but with their diverse starting points, is there any way to analyse Critical Legal Studies approaches save in terms of what they are against?

One possibility is to locate Critical Legal Studies within the 'dialectic of the Enlightenment' and in particular the fragmentation of the Enlightenment project after Hegel and Marx. The breakdown of the Hegelian synthesis between legal and rational thought, together with the impact of Marxism, led in the nineteenth century to a threefold division in thinking about law and philosophy. What followed was a complex development with many overlapping strands, but one can identify schematically three theoretical approaches in order to locate Critical Legal Studies. The first is the development of positivist modes of thought which discarded the need for an external, overall system of philosophical reason with which to legitimate law's operation (the positivist approach) (see Positivism in the social sciences). Second, within ethical philosophy and critical theory, rationalist thought was subjected to increasing scrutiny and subversion (the approach of philosophical critique) (see Critical theory). Third, with Marxism, a historical and materialist method was developed that sought to understand both law and reason as expressions of historically developed social relations (the approach of sociological critique) (see Socialism). These three different approaches to social theory and law constitute the parameters within which Critical Legal Studies operate.

Drawing on the second and third approaches, Critical Legal Studies provides a critique of the idea that law and legal reasoning can be understood independently of broader social, moral and political questions, so that the positivist developments of the nineteenth century (the first approach), together with their modern derivatives, are a primary target. It is this target that gives Critical Legal Studies what unity it has; thereafter, the adoption of any critical perspective is a rather 'free' matter of picking from the range of critical resources available within Marxist and post-Enlightenment political philosophy (the second and third approaches). Because of its leftist political interests and its roots in 1970s social movements, Critical Legal Studies has always drawn significantly upon

Marxism, but more recently there has been a greater emphasis on the method of deconstruction and the work of French post-structuralists such as Foucault, Levinas, Derrida and Lyotard. While the relationship between post-structuralism and Marxism is controversial, these critical approaches have in common a desire to relate law to an ‘outside’ or a ‘beyond’ and to deny its autonomy. In Derrida (1990), the assertion of ‘the other’ as the beyond of law is explicit, while in Marxism, the external is to be found in the social relations of which law is a specific part, but which it also helps to constitute. In contrast to these trends, however, it should be noted that the German approaches as represented by Habermas (at least in his more recent (1988) work; see also Murphy 1989) and autopoietic theory seek to establish a critical basis ‘inside’ the law. Indeed in the latter case it is questionable how much more autopoiesis offers than a sociological variant of the Neo-Kantian positivist tradition in European legal philosophy.

The dialectic of the Enlightenment is both theoretical and historical. The radical rationalism of the Enlightenment became conservative in the work of Hegel, and then collapsed in the context of the ‘well ordered bourgeois state’. Legal positivism derived its strength from precisely this order, which was in important respects juridical. The role of theory came to be the ‘rational reconstruction’ (MacCormick 1993) of actual legal relations and practices, and legal positivism found its place within society and the academy as a result (Cotterrell 1983). Yet positivism was always vulnerable. Its linkage to the rationalization of a particular social practice (the law) created a tension with a range of social theories for which such a link was politically and intellectually problematic (see Legal reasoning and interpretation §3). Critical legal theory brings to bear a critical perspective on legal thought by exploiting this tension between positivistic legal-academic practice and broader social, moral and political concerns. It operates in the conflictual space between the three approaches established by the fragmentation of the Enlightenment project. So doing, it is able to expose legal thought to broader traditions in philosophy and sociology in ways that are at their best creative and critical. It remains on an ‘edge’ of legal-academic theory and practice and is vulnerable to changes in political and intellectual fashion. None the less it provides those who are justifiably dissatisfied with the narrow orthodoxy of traditional legal thought with some critical tools to go beyond the taken-for-granted reality of the mainstream.

5 The future

It is fitting to conclude an account of a new theoretical approach to law with consideration of its possible future directions. I discuss this in the Anglo-American context with reference to two reviews of Critical Legal Studies, one by an original US participant, the other by a recent British commentator.

Mark Tushnet (1991) offers a bleak picture of the current state of Critical Legal Studies in the USA. While he recognizes the need for a credible theoretical programme, he argues that Critical Legal Studies does not in fact have any essential intellectual components. Indeed he recommends that it be treated as a political rather than theoretical location for a left-leaning diaspora of feminists, critical race theorists, postmodernists, cultural radicals and political economists (see Feminist jurisprudence). What is more, the indeterminacy thesis at the heart of the original movement has now been to an extent both abandoned by its proponents and accepted by the mainstream. The gap between the two sides is now mainly one of degree. The only route forward that Tushnet suggests is a return to the classical social theory of Marx and Weber, but the recommendation is lukewarm. Yet if the indeterminacy thesis is partly abandoned by the critics and partly accepted by the mainstream, it is surely the question of how legal systems achieve determinacy under particular social and political conditions that becomes relevant. It is the historical analyses of classical social theory which consider such conditions and recognize the social and political significance of formalist and positivist concepts of law. These approaches therefore hold out the possibility of protecting Critical Legal Studies against absorption into a revised but still orthodox positivism. Tushnet outlines the theoretical process of engagement and disenchantment with Marx and Weber undergone by US critical theorists, but his account only confirms the pragmatic and populist nature and limits of that engagement. It therefore urges by implication a less half-hearted reappraisal of what such theories have to offer a critical legal project.

An alternative orientation to critical legal theory is provided by Peter Goodrich (1993) from within the present current of post-structuralist theory. He argues that critical thought ‘should investigate the conditions of possibility of the text and its interpretation’ (1993: 232). This involves, first, the use of history to reconstruct the intellectual development of the doctrinal tradition, leading to a recognition of the cultural specificity of forms of law, and a

critique of their modes of tradition, representation, repetition and reproduction. Second, such a historical perspective focuses on systems of classification, on conceptual grids and schemata, and on the forms of knowledge which pass as law. This represents a genuine programme for critical legal theory, but Goodrich's account raises questions about how it can be achieved. In particular, the relationship between the social history of legal forms and their critical interpretation remains problematic. In the concrete case of contract law, for example, Goodrich separates the 'historical' from the 'interpretive' stage of his critique. At the historical stage, he cites the existing institutional legal histories of contract, while the interpretive stage draws on literary theory or discourse analysis.

The result is an antinomian form of critique in which the first stage is undertheorized from a critical standpoint, and the second stage is abstractly theorized in a way that is unintegrated with the first. The critical punch of the second stage is provided by Goodrich's discussion of Carole Pateman's feminist criticism (1986) that the political social contract is also a sexual contract that marginalizes women, but nothing is said about the specifically legal institution discussed by the historians of contract. No doubt something could be said to link the two, but what is missing from, or marginalized within, Goodrich's account is any consideration of contract as a social phenomenon along the lines outlined by Marxism and Weber. Such accounts, which are nowadays sometimes treated as *passé*, none the less provide a substantial social and historical context within which the discourses of lawyers and legal historians can be read, and an important starting point for their critique. The point is not negatively to oppose classical social theory to postmodernism, but rather to ask how they can be fruitfully articulated, as surely they ought to be, in any analysis that seeks genuinely to be historically critical.

Treating these two reviews as representative of its current state of development, two dangers confront critical legal theory. The first is that, undertheorized, it will lose its distinctiveness and disappear into the mainstream. The second is that, abstractly theorized, it will lose the grip on law as a specific social and political phenomenon that Critical Legal Studies originally promised, but ultimately failed to deliver. A way beyond both these dangers is provided by a retrieval and integration of, but not an uncritical return to, the traditions of classical social theory represented by Weber and Marx (see Marxism, Western). If Critical Legal Studies does not address these in a more constructive way than it has done over the last decade it risks one of two fates. Either it will dissolve into the orthodox positivist tradition it sought to criticize, or it will lose itself in the abstract ethical theorizing that constitutes a large part of postmodernism.

Critical realism

Critical realism is a movement in philosophy and the human sciences starting from Roy Bhaskar's writings. It claims that causal laws state the tendencies of things grounded in their structures, not invariable conjunctions, which are rare outside experiments. Therefore, positivist accounts of science are wrong, but so is the refusal to explain the human world causally. Critical realism holds that there is more to 'what is' than 'what is known', more to powers than their use, and more to society than the individuals composing it. It rejects the widespread view that explanation is always neutral - to explain can be to criticize.

Bhaskar originally called his general philosophy of science 'transcendental realism' (see Bhaskar 1978) and his philosophy of the human sciences 'critical naturalism' (see Bhaskar 1979). The term 'critical realism' arose by elision of these two phrases, but Bhaskar and others in this movement have accepted it since 'critical', like 'transcendental', suggests parallels with Kant's philosophy, while 'realism' indicates the differences from it (see Kant, I. §5).

Critical realism starts from the transcendental question 'how are informative experiments possible?', which includes the question 'why are they necessary?'; that is, why can we not rely on spontaneous observations, but have to set up test-situations artificially, and how can these artificial tests disclose what happens spontaneously outside the laboratory? Bhaskar's answer is that experiments set up, as near as possible, 'closed systems', defined as systems in which something like Humean causation works: whenever A happens B happens.

In closed systems, particular mechanisms of nature can be isolated and studied accurately, but elsewhere in the open systems of which the world is made up, a multiplicity of these mechanisms co-determine events. Experimentally closed systems are of special value to science because they uncover mechanisms of nature, but these mechanisms are only of interest because they also operate in those open systems of which almost all the world consists, outside artificially contrived experimental conditions. Astronomy alone finds approximations to closed systems in nature, due to the lack of forces capable of deflecting heavenly bodies from their courses.

On this basis, critical realism postulates three kinds of 'depth' in nature, and identifies three common fallacies which arise from ignoring them.

(1) Not only may one distinguish, as common-sense realism does, between the contents of experience ('the empirical') and the actual course of events ('the actual'); one may also distinguish 'generative mechanisms' in nature, which are real even if not actualized. Gravity is real, even when the roof is not falling in. Failure to recognize this leads to 'actualism', the attempt to locate laws at the level of the actual (spontaneously occurring constant conjunctions). As against this, laws should be analysed as tendencies: bodies tend to persist in a state of rest or uniform motion in a straight line; hoppy beer tends to make you sleepy; capitalist enterprises tend to get bigger and fewer.
(2) The real multiplicity of natural mechanisms grounds a real plurality of sciences which study them. Even though one kind of mechanism may be explained by another (for instance, biological mechanisms by chemical ones), it may not be reduced to the other. Nature is stratified, with some strata rooted in but emergent from others; the course of events is different from what it would be if the more 'basic' strata alone existed. So the attempt to reduce human to natural or biological to physico-chemical science is ruled out by the nature of the subject-matter.
(3) Science is a social product, the result of experimental work; but the mechanisms it discovers operate in nature prior to and independently of their discovery. So we must distinguish the 'transitive object' of science - the knowledge it has produced - and its 'intransitive object' - the reality it is about, which exists independently of our knowledge, and always has unexplored depths to it. When this is not recognized, we fall into the 'epistemic fallacy', reducing questions about what is to questions about what we can know. Concepts like 'the empirical world' encapsulate this fallacy.

Several conclusions may be drawn for the human sciences.

(1) Most controversies between positivistic and hermeneutic views assume, on both sides, a positivist account of natural science (see Positivism in the social sciences §1). Therefore, positivists expect the human sciences to find constant conjunctions in the human world, though they are scarce enough in the natural; and hermeneuticists

conclude from the absence of such conjunctions that the human sciences are radically unlike the natural ones (see Social science, contemporary philosophy of §§1-3). A critical realist account of science makes possible a non-reductive naturalism in human science.
(2) Closed systems cannot even be established artificially in the human sciences. So experimental method is irrelevant here. More to the point are the detective-like skills of those natural scientists who study open systems: geologists, natural historians, meteorologists.
(3) Since we are humans, we have in our conceptualized social practices a ready-made starting point for the human sciences. This is the truth in hermeneutics. But there are no grounds either for regarding these data as infallible or for treating their operation as non-causal. Once we reject Humean causality and recognize emergence, we can accept that reasons for actions can be their causes - but also that they may be rationalizations of actions whose causes are elsewhere. Human sciences may be interpretive and non-reductive, but at the same time causally explanatory and corrective of agents' conceptions (psychoanalysis, Chomskyan linguistics and certain versions of Marxism seem to fit this model best) (see Chomsky, N.; Social science, history of philosophy of §12). This makes them potentially emancipatory, in that they can correct enslaving illusions (as psychoanalysis claims to), or illusions that subserve social oppression (compare Marx on ideology). In this connection, Bhaskar introduces the notion of an explanatory critique: some beliefs are incompatible with their own true explanation, and since this can apply to moral beliefs, the fact/value gap is bridged.

Critical realist interventions in debates about particular disciplines in the human sciences include Pateman (1987) on linguistics, Will (1980, 1984) on psychoanalysis, Collier (1989) on Marxism, and Soper (1995) on ecology.

Critical theory

The term 'critical theory' designates the approach to the study of society developed between 1930 and 1970 by the so-called 'Frankfurt School'. A group of theorists associated with the Institute for Social Research, the School was founded in Frankfurt, Germany in 1923. The three most important philosophers belonging to it were Max Horkheimer, Theodor Wiesengrund Adorno and Herbert Marcuse.

Horkheimer, Adorno and Marcuse feared that modern Western societies were turning into closed, totalitarian systems in which all individual autonomy was eliminated. In their earliest writings from the 1930s they presented this tendency towards totalitarianism as one result of the capitalist mode of production. In later accounts they give more prominence to the role of science and technology in modern society, and to the concomitant, purely 'instrumental', conception of reason. This conception of reason denies that there can be any such thing as inherently rational ends or goals for human action and asserts that reason is concerned exclusively with the choice of effective instruments or means for attaining arbitrary ends.

'Critical theory' was to be a form of resistance to contemporary society; its basic method was to be that of 'internal' or 'immanent' criticism. Every society, it was claimed, must be seen as making a tacit claim to substantive (and not merely instrumental) rationality; that is, making the claim that it allows its members to lead a good life. This claim gives critical theory a standard for criticism which is internal to the society being criticized. Critical theory demonstrates in what ways contemporary society fails to live up to its own claims. The conception of the good life to which each society makes tacit appeal in legitimizing itself will usually not be fully propositionally explicit, so any critical theory will have to begin by extracting a tacit conception of the good life from the beliefs, cultural artefacts and forms of experience present in the society in question. One of the particular difficulties confronting a critical theory of contemporary society is the disappearance of traditional substantive conceptions of the good life that could serve as a basis for internal criticism, and their replacement with the view that modern society needs no legitimation beyond simple reference to its actual efficient functioning, to its 'instrumental' rationality. The ideology of 'instrumental rationality' thus itself becomes a major target for critical theory.

1 Historical background

In 1923 a group of intellectuals in Frankfurt, Germany, founded an 'Institute for Social Research' as a centre for the interdisciplinary study of social and economic issues in contemporary society from a broadly socialist perspective. The term 'critical theory' is used to designate the approach to social theory developed by the members of the Institute (who came to be known collectively as 'The Frankfurt School') between 1930 and 1970. The philosophers most closely associated with the genesis of critical theory were Max Horkheimer, Theodor Wiesengrund Adorno and Herbert Marcuse. When the National Socialists seized power in Germany in 1933 the Institute moved to New York, where it remained until 1949. Much of the most original work of the Frankfurt School was produced during this period of exile in the USA.

In their early papers, Horkheimer and Marcuse outline the conception of an interdisciplinary social theory that would be guided by an interest in the normative goal of human emancipation. Translations of the most important papers from this period are collected in *Critical Theory* (Horkheimer 1968) and *Negations* (Marcuse 1968).

Although Horkheimer, Adorno and Marcuse took themselves to be rationalists (of a sort), in the 1940s they found themselves becoming increasingly sceptical of the Enlightenment assumption that scientific and technological progress is an unproblematic human good. Empirical science, they thought, was based on a form of rationality - 'instrumental rationality' - which was inherently manipulative and which would have disastrous social and moral consequences if not strictly subordinated to a more encompassing notion of rationality. The 'critique of instrumental reason' is elaborated most fully in The *Dialectic of Enlightenment*, written jointly by Adorno and Horkheimer and published in 1947. The 1940s also saw the completion of Adorno's *The Philosophy of Modern Music* (1949) and, in *Minima Moralia* (1951), his reflections on the impossibility of leading a good life in the contemporary world.

In 1949 Horkheimer negotiated a return of the Institute to Frankfurt. Marcuse, however, elected to remain in the

USA. During the 1950s and 1960s he held positions at various US universities and wrote the two books on which his reputation as a theorist of the New Left mainly rests: *Eros and Civilization* (1955) and *One-Dimensional Man* (1964).

Upon their return to Frankfurt Adorno and Horkheimer became prominent public figures, while continuing to practise their form of cultural criticism. In 1958 Horkheimer retired to Switzerland where he died in 1973. In 1966 Adorno published a lengthy philosophical account of his version of the critical theory, *Negative Dialectics*. He seems to have been surprised by the student movement of the 1960s. Many participants were inspired by his writings and thought of themselves as putting critical theory into practice, however Adorno repudiated their activism. In contrast, Marcuse attempted to the very end of his life to maintain a theoretical commitment to action for radical social change.

2 Conception of ‘theory’

Members of the Frankfurt School agreed in rejecting a widely held view about what a ‘theory’ is. In normal parlance a ‘theory’ is a set of formally specified and interconnected general propositions that can be used for the successful explanation and prediction of the phenomena in some object domain. This conception of theory, the members of the Frankfurt School argued, is extremely misleading because it directs attention away from the social context within which theories necessarily arise, are tested and are applied, and within which alone they are fully comprehensible. The term ‘theory’ should be used in the first instance to designate a form of (ideally social) activity with an especially salient cognitive component, and only derivatively for the propositions that might be formulated in the course of such activity. Human societies are engaged in a constant process of assimilating nature through labour in order to reproduce themselves; they develop forms of cognitive activity in order to make this self-reproduction more secure and more efficient. Horkheimer, Adorno and Marcuse call such cognitive activity ‘traditional theory’. Virtually everything we would in normal parlance call a theory (including all scientific theories) is what the members of the Frankfurt School would call a derivative form of traditional theory. However, they would claim there is another possible kind of cognitive activity, one which is not directed at reproducing society in its present form or making its assimilation of nature more efficient, but rather is directed at changing the existing society radically so as to make it more substantively rational. Essentially it is an attempt to do away with those fundamental features of the society that prevent agents from being able to lead a good life. ‘Critical theory’ is the name given to such inherently oppositional forms of thinking. In a derivative sense the propositions or specific theses brought forward by agents engaged in such oppositional thinking at some particular time may also be called critical theory. A critical theory thus is historically specific, being directed at a particular society that stunts the possible realization of the good life. It is inherently negative, and it depends on a conception of substantive reason.

3 Critique of instrumental reason

Critical theorists argue that in the ancient world the concept of ‘reason’ was an objective and normative one. Reason was thought to refer to a structure or order of what ought to be which was inherent in reality itself and which prescribed a certain way of life as objectively rational. Human beings were thought to have a (subjective) faculty which allowed them to perceive and respond to this objective structure of the world; this faculty could then also be called reason in a derivative sense. Even when ancient philosophers spoke of reason as a human faculty (rather than as a structure of the world), their conception of it was ‘substantive’; humans were thought to be able to use reason to determine which goals or ends of human action were worthy of pursuit.

In the post-Enlightenment world the ‘objective’ conception of reason becomes increasingly implausible. Reason comes to be conceived as essentially a subjective ability to find efficient means to arbitrarily given ends; that is, to whatever ends the agent in question happens to have. The very idea that there could be inherently rational ends is abandoned. Reason becomes subjective, formal and instrumental.

The historical process by which reason is instrumentalized is in some sense inevitable and irreversible. The philosophical position called ‘positivism’ draws from this the conclusion that reason itself should simply be identified with the kind of reason used in natural science. Scientific reason, the critical theorists claim, is a particularly highly developed form of instrumental reason. The point of getting an exact depiction of reality as it is and of the causal laws that govern events is to allow humans to manipulate the world successfully so as to attain

their ends. For this to be possible, the positivists believe, the terms that figure in significant scientific discourse must be clearly defined and their relation to possible confirming or disconfirming perceptual experience must be clearly specified. Reason, the positivists think, can be a guide to life only in a very limited sense. Its role is restricted to discharging three tasks: (1) it can criticize a set of beliefs and ends for failing to satisfy certain minimal principles of logical consistency; (2) it can criticize a given choice of means towards a given end on a variety of possible empirical grounds, such as that the means in question will not actually lead to the envisaged end or will have undesirable side effects, and it can propose more appropriate means; (3) it can unmask inherently non-cognitive beliefs, for instance value judgments, that are presenting themselves as if they had cognitive content. The role of reason in discharging the third of these tasks is especially important in the view of the positivists because any statements that do not belong to the descriptive and explanatory apparatus of science, and in particular any statement about what ought to be the case, stand wholly outside the domain of rational argumentation and can be nothing but the expression of arbitrary choice or personal preference (see Positivism in the social sciences).

Critical theorists think that this line of argument is seductive, but dangerous and false. Although it is true that reason cannot directly prescribe some set of ends as inherently rational and worthy of pursuit for their own sake, it retains an essential function that goes beyond those the positivists would allow it. This further function is that of ‘internal’ or ‘immanent’ criticism.

4 Internal or immanent criticism

To understand the Frankfurt School’s doctrine of internal criticism it is necessary to see it in the context of their general conception of society. Horkheimer, Adorno and Marcuse reject all four components of the positivist approach to the study of human society:

1 the view that human societies are just bundles of separate facts, events and institutions (‘atomism’);
2 the view that social facts and institutions are what they are regardless of what people think of them (‘objectivism’);
3 the view that the concepts we use to give an account of a society are just tools which we are free to define in whatever way seems convenient (‘nominalism’);
4 the view that the concepts we form should be purely descriptive, that is, defined exclusively in terms of purely observable properties with no evaluative component (‘the fact/value distinction’).

Contrary to this, members of the Frankfurt School hold that every society is a ‘totality’ in which each feature is essentially connected with all others and that social reality is partly constituted by the forms of belief, understanding and evaluation that exist in the society in question. Thus atomism and objectivism are false. Furthermore, the actual practices and institutions in a society would make no sense unless they were seen as inherently oriented towards the realization of some socially specified conception of the good life. Thus the more naïve versions of the fact/value distinction are problematic for the study of societies. To use the favoured Hegelian terminology: each institution in a society must be seen in relation to its (objective) ‘concept’, an ideal form of itself which it aspires to approximate, thereby playing its assigned role in the realization of the good life. The concept of an institution is objective in that the agents who participate in the institution need not be fully and explicitly aware of it - it cannot be determined by simply reading off the contents of their beliefs. It is also objective in that if we as researchers fail to formulate the concept correctly, we will have misunderstood the institution in question fundamentally. Thus ‘nominalism’ in the study of society is wrong, too. Although the concept of a social institution is objective in this sense, it is not, of course, objective in the sense in which a natural phenomenon is; it is *finally* constituted by human subjects and their activities, although this process of ‘constitution’ may be a very highly mediated one, lasting through a long historical time. To discover the concept is a very complex, constructive, theoretical activity requiring the social philosopher to enter into the history of the institution and study the ways in which people in the past understood it, the hopes, aspirations and values that were associated with it and their consequences.

A critical theory elicits the concept of a given institution in a given society, formulates it and confronts the actual reality of the institution with this ideal concept. There will be a discrepancy which the critical theory will point out and analyse. This analysis can be called internal or immanent criticism because the standards used in it are derived from the concept of the institution itself. Use of this internal method allows criticism to proceed without it being

necessary for the critic to have an unconditional commitment to or to give an independent justification of the standards of criticism used. The common view held by all the critical theorists until 1969 (the year of Adorno's death) was that substantive reason in the modern world must remain relentlessly negative: one cannot extract from reason the image of a good society or indeed any unconditional set of positive ideals. Reason cannot describe utopia, but can at best specify a 'determinate negation' of some particular feature of contemporary society that has been subject to internal criticism. Just as Marx does not describe the socio-economic formation he believes will succeed capitalism in positive and detailed terms, but only in negative terms as a 'class-*less* society', so similarly the most Adorno is ever willing to assert is that it would be desirable to be able 'to be different without *angst*' (1951: 656). In 1969 Marcuse announced (in the 'Introduction' to *An Essay on Liberation*) that he was breaking with the prohibition on utopian speculation that had been an integral part of the original critical theory; his post-1969 views will be discussed below (see §7) (see Utopianism).

5 The dialectic of enlightenment

Horkheimer and Adorno held that the final framework for social criticism had to be a speculative philosophy of history. In *The Dialectic of Enlightenment* (1947) they set out to provide the global interpretation of human history they believe is necessary.

Human history is a dialectic of 'enlightenment' on the one hand and 'myth/barbarism' on the other. 'Enlightenment' as used by Adorno and Horkheimer means both: (1) a certain theory - that is a specification of goals for society, a set of views about individual morality, the nature of knowledge, rationality and so on; and (2) the actual state of society which results from the massive application of this theory. 'Myth' is the opposite of enlightenment in sense (1); 'barbarism' the opposite of enlightenment in sense (2).

Enlightenment as a theory comprises five central tenets.

1 Commitment to certain ideals; autonomy, individuality, non-coercion, human happiness and so on.
2 Commitment to the view that 'genuine' knowledge is knowledge that is (a) 'objectifying', based on a clear and strict separation between the human subject and nature (as object of knowledge); (b) 'identifying', subsuming individual instances (of whatever it is that is to be known) under unitary general concepts and thus presenting them as in some sense 'the same'; (c) inherently technologically or instrumentally efficacious.
3 Commitment to the view that an increase in genuine knowledge in a society would lead to a greater realization of the ideals of the Enlightenment (as formulated in 1 above).
4 Commitment to a principle of universal criticism; that is nothing is to be taken on faith or authority or because of ' tradition' but every belief must show a warrant that will be recognized by the Tribunal of Reason.
5 Commitment to seeing itself (that is, to seeing enlightenment) as absolutely different from and opposed to barbarism and myth.

Horkheimer and Adorno have a number of criticisms of this theoretical position. First of all they claim that item 5 is false. The enlightenment is wrong to see itself as utterly and radically different from myth. Rather the relation between myth and enlightenment is a 'dialectical' one. Both have a common origin as reactions to the same phenomenon: primeval terror. Human history in fact is nothing but a series of attempts to deal with our overwhelming fear of what is other or unknown. Myth arises from a mimetic reaction to this terror: by making ourselves like that which we fear, by identifying with it, we attempt to do away with its otherness, as primitive hunters might try to deal with their fear of a predator by mimicking its movements in a dance. Another way to react to fear of the unknown is by separating it strictly from the self and subjecting it to a system of identifying categories the better to keep track of it and perhaps eventually control it. This second reaction is that of enlightenment: a rigid fixation on self-preservation as the absolute overriding goal and an incipiently paranoid concern to classify everything so as to be able to subordinate it to the attainment of that goal. Looked at, then, from sufficient distance enlightenment and myth seem similar. Both are attempts to use a form of identity to deal with the *angst* induced by difference. The direction (as it were) of 'identification' runs, however, in the opposite direction in the two cases. In myth we make ourselves like the other; in enlightenment we try to make the other like our category (by subsuming it). Close inspection of myths moreover reveals them to be historically superseded forms of enlightenment. The pantheon of Olympian gods - archetype of mythic thinking in the West - is not just a creation of the mimetic impulse, but must also be seen as a form of enlightenment relative to the religious beliefs

and practices associated with the nameless, chthonic deities of pre-Homeric Greece. What counts as myth and what as enlightenment is not given absolutely once and for all, but is historically relative.

Adorno and Horkheimer's second criticism is that the enlightenment tends to overlook or downplay the price humanity has had to pay for enlightenment. The instrumentally manipulative attitude the enlightenment bids us adopt towards nature will necessarily tend to extend itself to our relations with our fellow humans. Furthermore, effective instrumental control of nature requires that I control and finally repress my own spontaneity. Spontaneity is, however, an essential part of a human's capacity for happiness. Modern subjectivity itself is a result of this process of enlightenment, in which self-preservation is ensured at the cost of impairing our capacity for happiness.

The third line of criticism is that enlightenment has an inherent tendency to destroy itself. The original substantive ideals of the enlightenment (autonomy, individuality and so on) are not themselves exempt from the demands of the principle of universal criticism; that is, from the requirement of giving an account of themselves before the Tribunal of Reason. It becomes increasingly clear, however, that it is not possible to argue from the results of empirical science or from some more general principles of instrumental reason (that is, from some bit of what the enlightenment itself would consider 'genuine knowledge') to the validity of those ideals. In the end the ideals themselves come to look like myths or prejudices which ought to be discarded. The Marquis de Sade, a legitimate child of the enlightenment, finds no 'rational' arguments against cruelty (and much to be said in its favour).

Fourth, the history of the twentieth century has shown that the increase in technological control over the world and the spread of scientific knowledge does not in fact necessarily make people more autonomous, more highly individuated or more happy.

Their final criticism starts from the rigidity and paranoia of the enlightenment project, from its need to encompass *everything* in a single, definitive, closed system of concepts. This means that enlightenment is potentially totalitarian and has an inherent tendency to absolutize itself; that is, (falsely) to declare itself to be not just a given historically relative stage in the global process of enlightenment, but rather the final and definitive form of enlightenment. In thus absolutizing itself and resisting change, the given stage of enlightenment turns itself into a form of myth. This transformation is the final stage of the 'dialectic of enlightenment'.

Despite this battery of criticisms Horkheimer and Adorno do not reject the enlightenment outright. Rather they see their task as one of furthering the underlying enlightenment project by enlightening the enlightenment about itself. By analysing its inherent tendency towards totalitarianism, they hope to save its ideals (even if only in negative form) and prevent it from turning itself into a form of myth and barbarism (see Totalitarianism §4).

6 Negative dialectics

In his *Negative Dialectics* (1966), Adorno tries to give a philosophical account of the kind of thinking that is constitutive of critical theory: a form of substantive reason which is however purely negative.

Both everyday thinking and science, he claims, proceed by subsuming particulars under general concepts. By doing this, however - by claiming that *this* (tree) is a tree and that *that* (tree) is (also) a tree - we are tacitly asserting an identity between the two individuals and between each individual and the concept. To engage in such 'identity thinking' is to be tacitly trying to make identical what is in fact in some sense different - no two trees are exactly alike. Using an identifying concept is a way of trying to crush or suppress difference. The appropriate form of resistance to this reprehensible project is to remain aware of 'non-identity'; that is, of the ways in which instances are not identical with the concepts under which they are subsumed (and with each other). 'Negative dialectics' tacks back and forth between concept and instances, continually pointing out in what concrete ways they are not identical. Such a negative dialectics is a kind of cognition of the non-identical, although the process of moving back and forth negatively between concept and instance has no natural stopping point and will not ever result in some positive, detachable conclusion or new, more adequate concept.

Adorno rejected the usual standards of clarity and communicability for philosophical writing, seeing in them forms of repression, ways of preventing novel thoughts from being thought. He thus consciously wrote in an elusive, convoluted style, and claimed that (his) philosophy could not be summarized. This view makes good sense if one thinks of philosophy as essentially a concrete attempt to specify a 'determinate negation' that cannot in principle be turned into anything positive.

7 Conclusion

The philosophy of art had always played an important part in Adorno's thinking. Art and philosophical reflection on it form one of the few remaining oases for the play of free, spontaneous, human subjectivity in an increasingly regimented world. By the end of the 1960s, however, it had become hard to see how such reflection on high art, negative dialectics or the meditative essays on religion, pessimism and the philosophy of Schopenhauer Horkheimer had begun writing could be seen as part of the 'self consciousness of a revolutionary process of social change', or indeed how the late form of critical theory could be connected with any kind of action at all.

Toward the end of the 1960s Marcuse tried to break out of this impasse by giving up the traditional self-imposed ban among the members of the Frankfurt School on giving a 'positive' theory of any kind or engaging in utopian speculation (see §4). In *An Essay on Liberation* (1969) and *Counter-Revolution and Revolt* (1972) Marcuse claimed that the modern world had brought into existence a 'new sensibility' which he saw expressed most clearly in the emerging student counter-culture. This 'new sensibility', with its demand for aesthetically satisfying forms of immediate experience and its refusal to participate in consumer society, represented a significant new political force in the world. The social change necessary to accommodate the 'new sensibility' had become a vital individual need, and so one could even speak of a 'biological foundation for socialism'.

Since the mid-1960s a group of younger philosophers, most notably Jürgen Habermas, have tried to develop further some of the central components of critical theory. Although there are many similarities between the work of this second-generation of Frankfurt philosophers and the programme of critical theory, there are also some striking and important differences. In a sense the second generation marks a return to the kind of Neo-Kantian philosophy the critical theorists of the 1930s were reacting against. Adorno in particular was uncompromising in his opposition to the idea that philosophy should consist of a closed system of interconnected propositions that rested on a purportedly firm foundation and claimed universal validity. In the work of Habermas and his associates, however, the Kantian themes of finding a fixed universal framework for theorizing, giving firm foundations for knowledge claims of various sorts, and investigating the conditions of the possibility of various human activities, structure much of the discussion.

In retrospect the most important contribution of critical theory to philosophy in the late twentieth century would seem to be their criticism of positivism and their demand that social theory be reflective; that is, that theorists try to be as aware as possible of their own position, the origin of their beliefs and attitudes, and the possible consequences their theorizing might have on what they are studying.

Croce, Benedetto (1866-1952)

The leading Italian philosopher of his day, Croce presented his philosophy as a humanist alternative to the consolations of religion. A Hegelian idealist, he argued that all human activity was orientated towards either the Beautiful, the True, the Useful or the Good. These ideals were the four aspects of what, following Hegel, he termed spirit or human consciousness. The first two corresponded to the theoretical dimensions of spirit, namely intuition and logic respectively, the last two to spirit's practical aspects of economic and ethical willing. He contended that the four eternal ideals were 'pure concepts' whose content derived from human thought and action. Spirit or consciousness progressively unfolded through human history as our ideas of beauty, truth, usefulness and morality were steadily reworked and developed.

Croce insisted that his idealism was a form of 'absolute historicism', since it involved the claim that all meaning and value evolved immanently through the historical process. He strenuously denied that spirit could be regarded as some form of transcendent puppet-master that existed apart from the human beings through which it expressed itself. He accused Hegel of making this mistake. He also maintained that Hegel's conception of the dialectic as a synthesis of opposites had paid insufficient attention to the need to retain the distinct moments of spirit. He argued that the Beautiful, the True, the Useful and the Good, though linked, ought never to be confused, and he criticized aestheticism and utilitarianism accordingly.

Croce developed his thesis both in philosophical works devoted to aesthetics, ethics, politics and the philosophy of history, and in detailed historical studies of Italian and European literature, culture, politics and society. Opposition to the Fascist regime led him to identify his philosophy with liberalism on the grounds that it emphasized the creativity and autonomy of the individual. In practical politics, however, he was a conservative.

1 Life and works

Born in 1866 at Pescasseroli, in the Abruzzi in Southern Italy, Croce's family were wealthy landowners; Croce himself never had to pursue a career. In 1883 his parents and sister were killed in an earthquake in which he too was buried. For the next three years he lived in Rome with his uncle, Silvio Spaventa, a prominent liberal statesman of the Cavourian party known as the Historical Right and brother of the prominent Hegelian philosopher Bertrando Spaventa, whose own political thinking also drew on Hegelian themes. Although Croce never took a degree, he attended lectures at Rome university, where he came under the influence of Antonio Labriola who introduced him to the writings of Johann Friedrich Herbart and later Karl Marx. Croce's political views reflected the conservative liberalism of his uncle, but he claimed never to have been attracted by Bertrando Spaventa's brand of Hegelianism or his doctrine of the ethical State. Herbart's Neo-Kantian position, in contrast, inspired his later theory of concept-formation, while his early studies of Marx led him to his view of the Useful as a category distinct from the Good, towards which most practical activity was aimed (see Herbart, J.F.; Marx, K. §11).

Resisting family pressure to enter the law, Croce left Rome in 1886 and settled in Naples, where he determined to become a private scholar. Initially he devoted his energies to numerous antiquarian studies centred on various aspects of southern Italian history in the sixteenth, seventeenth and eighteenth centuries. This research formed the basis of his later books on the Kingdom of Naples and the Baroque era in Italy. This period culminated in his study of Neapolitan theatre from the Renaissance to the Enlightenment, published in 1891. The fusion of cultural and social history in these early writings was highly innovative and contained the germs of many of his later philosophical preoccupations - particularly with respect to the nature of human creativity and action.

These theoretical concerns began to come to the fore when in 1893 he published his first essay in philosophy, 'La storia ridotto sotto il concetto generale dell'arte' (History Subsumed under the General Concept of Art). Croce used an article by the Italian positivist Pasquale Villari entitled 'Is History a Science?' as an excuse both to attack the positivism then dominant in Italy and to enter the contemporary German debate between Windelband and Dilthey over the identity of the human sciences (see Dilthey, W. §3; History, philosophy of §4). Croce argued that while history was like art in representing particular events rather than elaborating general laws, as in the natural sciences, it differed in dealing with what actually occurred, rather than with what might have happened. Prompted by Labriola, he followed up this essay with a number of articles attacking crude quasi-Darwinian materialist interpretations of Marxism, although he went beyond his brief to criticize Marx's economic doctrines as well.

These writings, collected together in book form in 1900 as *Materialismo storico ed economia marxista (Historical Materialism and the Economics of Karl Marx)*, brought him to the attention of an international public including Georges Sorel and Vilfredo Pareto, whose interpretation of Marxism as a secular religion he came to share. His friendship with Giovanni Gentile, then working on a doctoral dissertation on Marx's philosophy, also began at this time (see Gentile, G. §1). Their collaboration over the next twenty years was to transform Italian philosophy, producing a revival of Hegelian Idealism.

In 1903 Croce began to publish his bimonthly journal *La critica*, devoted to reviews of the latest Italian and European books in the humanities and including general surveys of Italian literature and philosophy since unification written by Croce and Gentile respectively. Croce's *Estetica come scienza dell'espressione e linguistica generale (Aesthetic)* had appeared in 1902. This book became the first volume of his *Philosophy of Spirit*, and was followed by his *Logica come scienza del concetto puro (Logic)* (1905, completely reworked in 1909), the *Filosofia della pratica. Economia ed etica (Philosophy of the Practical)* (1909), and the *Teoria e storia della storiografia (Theory and History of Historiography)* (1917). Prompted by Gentile, Croce's philosophy took an increasingly historicist direction from 1905 onwards, a shift that led to the rewriting of the *Logica*). This development also prompted him to write detailed studies of Hegel, *Cio che è vivo e cio che è morto nella filosofia di Hegel (What is Living and What is Dead in the Philosophy of Hegel)* (1907), and of Vico, *La filosofia di Giambattista Vico (The Philosophy of Giambattista Vico*) (1911).

Croce became a life senator in 1910 but only began to write on and participate in politics with the advent of First World War, when he campaigned for Italy to remain neutral. He acted as Minister of Education in the last cabinet of the liberal politician Giovanni Giolitti from 1920 to 1921, putting forward reforms in schools and higher education that he and Gentile in particular had long advocated and which were finally implemented in the Fascist *Riforma Gentile*. Sympathetic to Fascism as long as he felt it was controlled by the old liberal elite as a bulwark against socialism, he never subscribed to its ideology and broke with it after 1924. Relations with Gentile, already strained due to his aversion to his friend's extreme subjectivist 'actual' idealism, finally collapsed with the latter's entry into the Fascist Party, of which he became the self-styled philosopher. Croce became a leading opponent of the regime, penning a famous protest against Gentile's *'Manifesto of Fascist Intellectuals'* in 1925. Opposition gave him a new lease of life and led him to characterize his philosophy as a form of liberalism - most particularly in two series of essays: *Etica e politica (Politics and Morals)* written largely in 1924-8 and collected in 1931, in which he put forward his ethico-political theory of history, and *La storia come pensiero e come azione (History as the Story of Liberty*) (1938), where he defined history as the 'story of liberty'. He also illustrated these theses in four historical studies: *La storia del regno di Napoli (A History of the Kingdom of Naples)* (1925), *Storia d'Italia dal 1871-1915 (History of Italy 1871-1915)* (1928a), *Storia dell'eta barocca in Italia (A History of the Baroque Era in Italy)* (1929) and *Storia d'Europa nel secolo XIX (History of Europe in the Nineteenth Century)* (1932). He made corresponding changes to his aesthetic doctrine, culminating in *La poesia (Poetry)* in 1936. Only the allied invasion caused him to stop publishing *La critica*, and he continued to produce books and essays and occasional *Quaderni della critica* right up to his death in 1952.

2 Aesthetics

Croce's aesthetics were tied both to his activity as a literary critic, which was copious, and developments in his general philosophy. He confessed to having no appreciation of music and wrote comparatively little on architecture or the figurative arts, leading some commentators to suggest that his theory is biased towards poetry. As the major influences on his own thinking, he claimed Francesco De Sanctis, whose *La storia della letteratura italiana (History of Italian Literature)* (1870-1) he continued through to the late nineteenth and early twentieth centuries, and Giambattista Vico, whose aesthetic thought he first brought to prominence.

Commentators commonly identify four phases within Croce's aesthetic doctrine, roughly corresponding to changes in his philosophy, although opinions differ over their compatibility with each other. The first phase, associated with the *Aesthetic* of 1902, consists of Croce's identification of art with intuition. His main targets were positivist or empiricist theories, on the one hand, and intellectualist or rationalist views on the other. Against the first, he claimed that feeling and emotion have to be expressed to have any existence, and that this is a cognitive process. Against the second, he distinguished logical from intuitive knowledge. Whereas the former works through concepts and deals with universal relations between things, the latter is obtained through images of particular

things. Adopting a Herbartian reading of Kant, he argued that we organize the world of experience and sensation through the intuitive faculty of the imagination that gave expression to them. Form and content, intuition and expression were identical. That which was not expressed had not been intuited and remained ‘a mere natural fact’. The logical categorization of this intuitive knowledge was a subsequent stage. He also contended that the theoretical activity of the imagination was distinct from any practical or ethical purpose. True art, therefore, was concerned neither with the True, the Useful or the Good - an argument he deployed against the Italian *verismo* school of naturalist writers influenced by Emile Zola.

The second phase of Croce’s aesthetics came with his theory of the lyrical nature of art. First enunciated in an article of 1908, and subsequently elaborated in the *Breviario di estetica (The Essence of Aesthetic)* (1913), this doctrine attempted to specify further just what artistic expression consisted of: namely the lyrical intuition of ‘intense feelings’ or emotions. Such feelings, he still insisted, could not be described in sensationist terms, but could only be expressed through images. For analogous reasons, he also rejected romantic theories that treated art as no more than a spontaneous outpouring of emotion. Art is a spiritual activity that transforms our bare animal existence. However, he continued to distinguish the images of intuition from the categories of logical thought, and he criticized the artificial canons and rules of classical theorists for ignoring this fact.

While distinct from either philosophy or practice, art was related to them. Drawing on his contemporaneous revision of Hegel and the resulting thesis that spirit evolved via a dialectic of distincts rather than of opposites, Croce argued that intuition tends to give way to perception and so to conceptual thought or judgment. Furthermore, such knowledge leads us to take up a new attitude to life and so affects our practice. This new will in its turn solicits new passions and feelings that find expression in a new lyric and fresh art, constituting a process which Croce termed the ‘circle of spirit’, in which each moment is both independent and dependent, condition and conditioned.

The third phase of Croce’s aesthetics builds on this thesis by insisting on the ‘cosmic’ or ‘universal’ character of art. Put forward in his article ‘Il carattere di totalità dell’espressione artistica’ (The Totality of Artistic Expression) (1918a), this doctrine served to underline the cognitive aspect of his theory by stressing that as an aspect of spirit ‘every genuine artistic representation is itself and is the universe, the universe in that individual form’ (1926: 122). However, intuition formed only a part of the ‘circle of spirit’, and he rebutted criticisms of mysticism or aestheticism which accused him of reducing all knowledge to artistic intuition. Nevertheless, at this time Croce tended to reify spirit and treat human activity as a mere manifestation of its unfolding, a position he later rectified. Croce illustrated his argument in studies of *Goethe* (1919a), *Ariosto, Shakespeare, Corneille* (1920) and *La poesia di Dante (The Poetry of Dante)* (1921).

The final phase was signalled by *La poesia* (1936). Croce regarded this book as incorporating all the subsequent revisions of his aesthetic theory and replacing the *Aesthetic* of 1902. He argued that there were four types of ‘expression’: the ‘sentimental or immediate’, the ‘poetic’, the ‘prosaic’ and the ‘rhetorical’. True poetry, he argued, only arose when these types originated from a ‘lyrical expression’ and had no ulterior utilitarian, moral or philosophical purpose. When lyricism was absent, one had literature, which he further subdivided into the sentimental, moralistic, entertaining or instructive.

3 Logic and history

Croce’s *Logic* centred on his notion of the ‘pure concept’ as a universal idea that could not be confused with the particular representations it encompassed. As such, it was to be distinguished from ‘pseudo-concepts’, which were mere classes of objects. These latter were empirical rather than theoretical categories.

The content of ‘pure concepts’ came through history. The identification of history and philosophy in the second edition of the *Logic* (1909) was the most important revision Croce was to make to his theory. Judgment, he argued, is essentially historical in nature, involving the union of a pure universal concept with a historically given particular object. When we say ‘Peter is a man’ we not only define a characteristic of Peter with a preformed concept of what a man is, we reaffirm and change the concept of man in relation to Peter. Our notions of maleness are historical products of past meetings with other Peters and Pauls, and modifiable by other future encounters. Similarly, Peter’s conception of himself was equally defined by a given notion of man. In this way, Croce argued, philosophy proved both conditioned by history and a means, through conceptual innovation, for the making of new

history. Likewise, theory and practice are mutually related, the one influencing the other.

Croce carried this thesis further in the final volume of the *Philosophy of Spirit*, the *Theory and History of Historiography*. Here he famously claimed that ' All history is contemporary history' because 'it meets a present need' (1917: 5-17). The collection of facts about the past, while a necessary preliminary for historical writing, was not yet history but 'chronicle'. It was a 'dead' past because it had yet to be interpreted and given a meaning. Interpretation involved entering the minds of the historical actors and understanding the inner significance of their actions by reliving these events in the historian's own consciousness. Croce believed that this was possible because we are what our past has made us, so that our knowledge of ourselves is historically conditioned. The past literally lives within us.

Croce was careful to avoid any suggestion of relativism or subjectivism. He denied that history was whatever we took it to be. Indeed, at times he appeared to argue that it was not so much individuals, as spirit 'eternally individualizing itself' that was the true subject of history. This thesis, together with his contention that we are all products of the past, risked denying individuals the possibility for any creative action at all. During the 1920s and 1930s he modified his position on both these fronts. In a series of essays written in 1922-4, he proposed the view that history was 'ethico-political' in nature. In other words, the conflict of different individual ideals was the true dynamic of history, a view he deployed against both Marxism and Fascism. Historicism, therefore, buttressed liberalism. He was not thereby advocating voluntarism, however. As he made clear in his final major work, *History as the Story of Liberty*, successful action depends on a correct appraisal of one's current situation - itself a matter of historical judgment. Knowing the world in thought gives an impetus to the ethical desire to transform it through action.

4 Ethics and politics

Croce's initial concern in the field of practical philosophy was to distinguish the concepts of the Useful and the Good and to combat both utilitarian moralities and moralistic politics as category mistakes. Although this distinction figured in his writings on Marx and formed the basis of an influential debate with Vilfredo Pareto on the relation of economics to ethics, he did not expound it fully until the *Filosofia della pratica: economia ed etica*, where he integrated it into his general theory of the circle of spirit within history.

He did not draw any practical inferences from this doctrine until the First World War. In a series of articles later collected as *Pagine sulla guerra (Writings on the War)* (1919b), he attacked those who maintained that the war was between two rival moralities - the democratic and the autocratic. Croce contended that war, like politics in general, was pre-moral in being orientated towards the Useful. The state had no purpose but that of power and no means other than force, so that the military struggle should be seen as a matter of pure *realpolitik*. He strenuously denied that this view entailed identifying might with right. However, in essays published as *Frammenti di etica (The Conduct of Life)* (1922), he did insist that morality was not something that could be pursued directly, but was a matter of the judgment of history. Accordingly, he argued that each person should simply fulfil the duties of their appointed station and trust in Providence.

The dangers of this deeply conservative position became evident with the rise of Fascism (see Fascism). Croce initially supported it, albeit lukewarmly, as leading to a strengthening of the state. However, Gentile, now a keen supporter of Fascism, made precisely the jump that Croce feared of identifying the force of the state with its moral strength. This move, and his resulting doctrine of the ethical state, led Croce to clarify his position. He accused Gentile and the Fascists of putting forward a 'governmental morality'. While he continued to regard the state in the narrow sense as belonging to the realm of the Useful, he now maintained that politics in general had an ethical dimension in the struggle to realize certain ideals and he endorsed liberal democracy for allowing the widest possible competition between different points of view. However, he claimed his liberalism to be 'metapolitical' rather than narrowly party political. While he believed that liberalism entailed a free market in ideas, he argued that different economic and political policies might be appropriate in different historical circumstances - even communism. This argument provoked a debate with the economist Luigi Einaudi over whether moral and political liberalism entailed libertarianism. Against Einaudi, Croce maintained that economic liberals erred in attempting to categorize everything in terms of the Useful and so failed to see that liberalism was the dialectic of spirit in all of its moments throughout the whole of history. Croce made the same criticism of left-of-centre liberals such as Guido Calogero and Guido de Ruggiero, who campaigned for a social welfare view

of liberalism similar to that of the English New Liberals, such as L.T. Hobhouse. While Croce's 'metapolitical' position proved useful in uniting the various opponents of Fascism, it yielded little except a certain pragmatism when it came to practical politics. After the war, Croce acted as President of a new formed Liberal Party. However, he was unable to forge a broad non-Catholic non-Socialist bloc, as he had hoped. Instead, he found himself presiding over an increasingly right-wing party and ultimately resigned.

The shifts in Croce's politics highlight a constant tension in his philosophy as a whole between historicism and idealism, realism and rationalism, politics and ethics, the Hegelian and the Kantian aspects of his thought. In some respects, his chief claim was to have made a virtue out of this tension, rather than attempting to synthesize these two elements. The constant revisions that his thought underwent, however, suggests that he found himself constantly pulled in different directions, emphasizing one then the other.

RICHARD BELLAMY

List of works

Croce, B. (1906-52) *Opere complete*, Bari: Laterza, 74 vols.(This excludes his correspondence and is not exhaustive. A National Edition is planned, and Adelphi Edizioni of Milan have recently published semi-critical editions of some of his more important works. Croce also made a selection of his works published in 1951 as *Filosofia-Poesia-Storia*, >Milan and Naples: Riccardo Ricciardi; trans. C. Sprigge, *Philosophy, Poetry, History: An Anthology of Essays*, London: Oxford University Press, 1966.)

Croce, B. (1891) *I teatri di Napoli del Secolo XV-XVIII (The Theatres of Naples from the Fifteenth to the Eighteenth Centuries)*, Naples: Pierro.(The culmination of Croce's only archival research into Neapolitan history of this period.)

Croce, B. (1893) 'La storia ridotto sotto il concetto generale dell'arte' (History Subsumed under the General Concept of Art), *Atti dell'Accademia Pontaniana* 24: 1-32. (Croce's first foray into philosophy.)

Croce, B. (1900) *Materialismo storico ed economia marxista*, Palermo: Sandron; trans. C.M. Meredith, *Historical Materialism and the Economics of Karl Marx*, London: Latimer, 1914.(Contains his critique of vulgar Marxism and Marxist economics, and his debate with Pareto.)

Croce, B. (1902) *Estetica come scienza dell'espressione e linguistica generale*, Milan, Palermo, Naples: Sandron; trans. D. Ainslie, *Aesthetic*, London: Macmillan, 1909; 2nd complete edn, 1922.(The first volume of his *Philosophy of Spirit*, which provides both the first version of his aesthetic doctrine and of his philosophy as a whole - each of which were subsequently much modified.)

Croce, B. (1905) *Logica come scienza del concetto puro*, Bari: Laterza; 2nd edn, 1909; trans. D. Ainslie, *Logic*, London: Macmillan, 1917.(The second volume of the *Philosophy of Spirit*. The changes to the second edition were occasioned by criticisms of the first by Gentile, whose influence is duly acknowledged, which led Croce in a more pronounced historicist direction.)

Croce, B. (1907) *Cio che è vivo e cio che è morto nella filosofia de Hegel*, Bari: Laterza; trans. D. Ainslie, *What Is Living and What Is Dead in the Philosophy of Hegel*, London: Macmillan, 1915.(A classic study of the German philosopher, which marked Croce's passage from a Neo-Kantian to a more Hegelian position, albeit with important reservations.)

Croce, B. (1909) *Filosofia della pratica, economia ed etica*, Bari: Laterza; trans. D. Ainslie, *Philosophy of the Practical*, London: Macmillan, 1913.(The third volume of the *Philosophy of Spirit*.)

Croce, B. (1911) *La filosofia de Giambattista Vico*, Bari: Laterza; trans. R.G. Collingwood, *The Philosophy of Giambattista Vico*, London: Latimer, 1913.(One of the earliest studies of the eighteenth-century Neapolitan philosopher, whose thought Croce did much to promote. As with his study of Hegel, his technique is to separate the living from the dead on the basis of those elements which are absorbed or rejected by his own philosophy.)

Croce, B. (1913) *Breviario de estetica*, Bari: Laterza; trans. D. Ainslie, *The Essence of Aesthetic*, London: Heinemann, 1921; first published in *The Book of the Opening of the Rice Institute*, Houston, TX, 1912.(Marks the second phase of his aesthetic doctrine.)

Croce, B. (1917) *Teoria e storia della storiografia*, Bari: Laterza; trans. D. Ainslie, *Theory and History of Historiography*, London: Harrop, 1921.(The fourth and final volume of his *Philosophy of Spirit*, in which he gives his first full exposition of his historicist views.)

Croce, B. (1918) *Contributo alla critica de me stesso*, privately printed in Naples for distribution to friends; trans.

R.G. Collingwood, *Autobiography*, Oxford: Clarendon Press, 1927.(Subsequently extended, and republished as an appendix to *Etica e politica*, it focuses on the evolution of his thought and takes Vico's *Autobiography* as its model. He periodically brought it up to date in later editions of *Etica e politica*.)

Croce, B. (1919a) *Goethe*, Bari: Laterza; trans. E. Anderson, London: Methuen, 1923.(A study of the German poet Goethe in which Croce seeks to illustrate his 'lyrical' account of poetic expression. The Italian edition included translations of his poetry by Croce.)

Croce, B. (1919b) *Pagine sulla guerra (Writings on the War)*, ed. G. Castellano, Naples: Ricciardi; 2nd expanded edn, Bari: Laterza, 1928.(A collection of journalistic pieces in which Croce advocated Italian neutrality and, once Italy had entered the war, argued for a realist view of politics, which he associated with Germany, against the idealist view he linked with the allies.)

Croce, B. (1920) *Ariosto, Shakespeare, Corneille*, Bari: Laterza; trans. D. Ainslie, New York: Holt, 1920. (Originally published separately, Croce employed these studies of three great dramatists to further develop his theory of poetry.)

Croce, B. (1921) *La poesia di Dante*, Bari: Laterza; trans. D. Ainslie, *The Poetry of Dante*, London: Macmillan, 1922.(A study of Dante's poetry.)

Croce, B. (1922) *Frammenti di etica*, Bari: Laterza; trans. A. Livingston, *The Conduct of Life*, New York, 1924. (Collects articles mainly written in 1915-18 which attempt to elaborate a historicist ethics against the background of the First World War.)

Croce, B. (1925) *La storia del regno de Napoli*, Bari: Laterza; trans. F. Frenaye, *History of the Kingdom of Naples*, Chicago, IL: Chicago University Press, 1970.(An attempt at 'ethico-political' history that focuses on the role played by intellectuals.)

Croce, B. (1926) *Nuovi saggi di estetica (New Essays on Aesthetics)*, 2nd edn, Bari: Laterza.(Collects together the various essays in which Croce progressively revised his philosophy of aesthetics. Includes 'Il carattere di totalità della espressione artistica' (1918).)

Croce, B. (1928a) *Storia d'Italia dal 1871 al 1915*, Bari: Laterza; trans. C.M. Ady, *History of Italy 1871-1915*, Oxford: Clarendon Press, 1929.(A defence of the liberal regime of Giolitti, with important chapters on the cultural life of the period.)

Croce, B. (1928b) *Aesthetica in nuce*, Bari: Laterza; trans. R.G. Collingwood, 'Aesthetics', in *Encyclopaedia Britannica*, New York and London, 14th edn, 1929, vol. 7.(The most accessible account of the third phase of Croce's aesthetic doctrine.)

Croce, B. (1929) *Storia dell'eta barocca in Italia (A History of the Baroque Era in Italy)*, Bari: Laterza. (Written in 1924-5 and published in instalments in *La critica* between 1924 and 1928, this was a path-breaking work that prompted study of a relatively neglected period of Italian history.)

Croce, B. (1931) *Etica e Politica*, Bari: Laterza; trans. S. Castiglione, *Politics and Morals*, London: Allen & Unwin, 1946.(Collects essays written in 1924-8, and represents Croce's attempt to defend a specifically liberal political order against Fascism and to revise his historicism in an 'ethico-political' direction that gave greater play to the creative action of individuals.)

Croce, B. (1932) *Storia d'Europa nel secolo XIX*, Bari: Laterza; trans. H. Furst, *History of Europe in the Nineteenth Century*, New York: Harcourt Brace, 1933.(The most 'philosophical' of Croce's histories, which is presented in terms of an apologia for the nineteenth-century liberal culture with which he strongly identified.)

(1936) *La poesia*, Bari: Laterza.(The final version of his aesthetic.)

(1938) *La storia come pensiero e come azione*, Bari: Laterza, trans S. Sprigge, *History as the Story of Liberty*, New York: W.W. Norton, 1941.(A major revision of his earlier historicism that links it firmly with a 'metapolitical' liberalism through its emphasis on the creative role of human thought and action.)

(1949) *My Philosophy, and Other Essays on the Moral and Political Problems of Our Time*, London: Allen & Unwin, selected by R. Klibansky, trans. E.F. Carritt.(A selection from Croce's later works.)

(1981) *Lettere a Giovanni Gentile (1896-1924)*, ed. A. Croce, Milan: Arnaldo Mondadori.(Contains invaluable accounts of his disagreements with Gentile that allows one to trace the development of his thought and the influence of his one-time colleague upon it. Gentile's letters are republished in his Collected Works.)

Crucial experiments

A 'crucial experiment' allegedly establishes the truth of one of a set of competing theories. Francis Bacon (1620) held that such experiments are frequent in the empirical sciences and are particularly important for terminating an investigation. These claims were denied by Pierre Duhem (1905), who maintained that crucial experiments are impossible in the physical sciences because they require a complete enumeration of all possible theories to explain a phenomenon - something that cannot be achieved. Despite Duhem, scientists frequently regard certain experiments as crucial in the sense that the experimental result helps make one theory among a set of competitors very probable and the others very improbable, given what is currently known.

Francis Bacon was the first to discuss the idea of a 'crucial experiment' at length. He called results of such experiments 'instances of the cross' (hence *experimentum crucis*), borrowing our metaphor from the crosses erected where two roads meet to point out the different directions. Bacon claimed that such decisive instances are to be found both among ones already obtained and, more frequently, among new ones produced expressly for that purpose. He offered several scientific examples, including experiments to decide between competing theories of the tides, of the apparent diurnal rotation of the heavens, of the weight of bodies, of magnetism, and of exploding gunpowder. According to Bacon (1620), such experiments 'afford great light, and are of great weight, so that the course of interpretation sometimes terminates, and is completed in them'.

The most famous attack on the idea of crucial experiments was offered by Duhem, who boldly asserted (1905) that ' a "Crucial Experiment" is impossible in physics'. He gave two arguments. The first, an expression of Duhem's 'holistic' view of science, is that what is tested is not a single hypothesis or theory by itself, but a 'whole theoretical group', including assumptions regarding the laboratory instruments to be used in testing it. Secondly, and more importantly, even if only a 'theoretical group' rather than an individual hypothesis is tested, for a crucial experiment to be decisive:

> it would be necessary to enumerate completely the various [competing] hypotheses which may cover a determinate group of phenomena; but the physicist is never sure he has exhausted all the imaginable assumptions. The truth of a physical theory is not decided by heads or tails.
>
> (Duhem 1905: 190)

What lies behind the idea of a crucial experiment, according to Duhem, is an 'argument by elimination' with a form such as E_1:

(a) Some phenomenon O is observed.
(b) O can be explained by, and only by, exactly one of the theories $T_1, \ldots, T_n$.
(c) But $T_2, \ldots, T_n$ are false, because each entails some observable consequence which the crucial experiment shows to be false.
(d) So T_1 must be true.

In order to use such an argument, one must consider among $T_1, \ldots, T_n$ not just known theories, but all possible ones that could explain the phenomenon; and this, as Duhem points out, is impossible. If crucial experiments depend on such eliminative arguments, they must be impossible.

Yet scientists frequently do offer eliminative arguments, and of a form not subject to Duhem's major objection. In the early nineteenth century, proponents of the wave theory of light, such as Thomas Young and Augustin Fresnel, sought to establish their theory over the then entrenched particle theory by using an eliminative argument consisting of these steps: (1) Because light travels in space with a finite velocity, and the only known methods of communication of motion from one point in space to another are via the transference of bodies or the propagation of a wave disturbance through a medium, it is highly probable that light consists either of waves or of particles. (2) Some optical phenomena, for example, rectilinear propagation of light, reflection and refraction, can be shown to follow from both the wave and particle theories without difficulty. But in explaining certain other optical phenomena, most notably diffraction, the particle theory, but not the wave theory, introduces auxiliary assumptions that are very probable assuming the particle theory is true but very improbable given everything else

that is known. (3) Wave theorists conclude that, given what is known (including all the observed optical phenomena), the wave theory is highly probable (see Achinstein 1991) (see Optics §1).

This argument is not refuted by Duhem's logical claims. Wave theorists do not assert, nor do they need to, that the particle and wave theories are the only *possible* ones (which is false, as was shown by twentieth-century quantum theory). They assert only that, relative to what is known at the time, it is highly probable that one theory or the other is true. And they offer reasons for this claim from known causes of motion. Their eliminative argument has a form expressed not by E_1 but by E_2:

(a) Some phenomenon O is observed.
(b) In the case of phenomena of the same type as O, the only known causes are C_1 and C_2; so probably either T_1 (which postulates cause C_1) or T_2 (which postulates C_2) is true.
(c) But T_2 is probably false because, in order to explain related phenomena, T_2, but not T_1, introduces auxiliary assumptions that although probable given T_2 are very improbable otherwise.
(d) So, given what is known, probably T_1 is true.

How do 'crucial experiments' enter the picture? Experiments that reveal phenomena which one theory but not the other explains without introducing highly improbable assumptions may be considered 'crucial' ones in establishing the high probability of the former theory. Fresnel's 1819 experiments on the diffraction of light showed the positions and intensities of the observed diffraction bands. These results were derivable from the wave theory without difficulty. To obtain them from the particle theory one had to introduce special forces acting at a distance that produce effects completely different from any ever observed in nature. Fresnel considered his experiments crucial in so far as they helped make the wave theory highly probable and the particle theory highly improbable.

PETER ACHINSTEIN

Crusius, Christian August (1715-75)

Crusius was a pivotal figure in the middle period of the German Enlightenment, linking Pufendorf and Thomasius with Kant. Though sometimes wrongly characterized (for example, by Hegel) as a Wolffian, he was instead an important critic of that position. His system reflected a new alliance between Pietism and Lutheran orthodoxy, offering a comprehensive antirationalist, realist, and voluntarist alternative to the neoscholastic tradition as renovated by Leibniz. Crusius was important in Kant's development and helps us understand the latter's philosophical Protestantism.

Born a pastor's son in Leuna bei Merseburg, in Saxony, Crusius was educated at Leipzig and much influenced there by the Thomasian professor A.F. Hoffmann (1703-41). Interested in both philosophy and theology throughout his career, he accepted a chair as extraordinary professor of philosophy at Leipzig in 1744. In 1750, however, he became ordinary professor of theology, also retaining his teaching post in philosophy until his death. His reputation as a philosopher peaked in Germany during the 1750s and 1760s, mainly on the basis of four scholastic manuals published in German during 1744-9. His greater theological reputation as founder of a 'biblico-prophetic' school emphasizing the inspirational unity of Scripture lasted well into the mid-nineteenth century.

1 Philosophical intentions

Crusius' works divide not only into philosophical and theological, but also into Latin and German. In the latter case, which includes his four scholastic manuals *Anweisung* (1744), *Entwurf* (1745), *Weg* (1747) and *Anleitung* (1749), there is disagreement over which are more important, and one gets differing accounts depending on their respective bases. The Latin essays, including *De usu et limitibus principii rationis determinantis (On the Use and Limits of the Principle of Determining Reason)* (1743), cover much the same ground as the manuals, but they are more focused, less didactic and together yield better insight into Crusius' philosophical concerns. Collected in revised form in the *Opuscula philosophico-theologica (Small Philosophical and Theological Works)* of 1750, most of them received approved German translations within a decade or two. Several works from Crusius' 'theological' period also help to clarify his notion of philosophy and its tasks. They include the *Epistola…de summis rationis principiis (Letter…on the Highest Principles of Reason)* (1752), *Dissertationes II-IV de superstitione (Discourses II-IV on Superstition)* (1766), *Kurzer Lehrbegriff der Moraltheologie (A Short Outline of Moral Theology)* (1772: vol. 1), and the prefaces to later editions of the manuals.

These sources reveal Crusius' opposition to 'the newer philosophy', which is inaccurately characterized as 'the Leibnizian-Wolffian system'. For Wolff himself rejected the term, claiming that he knew little of Leibniz when he wrote his so-called 'German Metaphysics' (1719), and Crusius did not use it until 1753 in the preface to the second edition of his *Entwurf*, having previously described the *praeceptor Germaniae* as a 'propagator of Leibnizian philosophy'. Leibniz and Wolff are often mentioned in the Latin writings (the manuals intentionally omit authorial references) and the similarities between them noted, but they are not regarded as having a joint system. Instead, the 'newer philosophy' consisted for Crusius of Leibnizian doctrines about sufficient reason, pre-established harmony, monadic substances, and the best of all possible worlds, with Wolff playing the role of systematizer and elaborator (see Leibniz, G.W.; Wolff, C.).

Carboncini (1986) suggests that Crusius saw the 'newer philosophy' as a general type. This emerges especially from the theological works, which link it with ancient superstition opposed to sound human understanding, particularly with Stoic fatalism. Beside this objection to its content, Crusius also criticized its syncretistic form and its methodological reliance on sectarian prejudices. His own philosophy, by contrast, emphasized freedom, clarity of concepts (rather than the formal necessity and certainty of arguments) and critical thinking for oneself. These notions link him with the Pietist, 'eclectic' tradition with which he has other, more specific affinities. They also suggest a connection between his philosophical and theological interests and provide a wider context for the needed developmental account of his thought.

2 Basic elements of Crusius' system

Since they were meant to counter Wolff's influence, Crusius' four scholastic manuals are themselves quite

Wolffian: thorough, explicit, systematic and full of definitions, multiple arguments and cross-references. They also address many topics treated by Wolff and clearly complement one another.

Least original among them is the *Anleitung*, which was the first Pietist tract to interpret nonliving nature in mechanistic terms, though Crusius still rejected Newtonian gravity. It also emphasized humans' merely hypothetical knowledge of basic natures and powers, and developed a position about the probable status of empirical generalizations or 'presumptions' (for example, nature makes no leaps) similar to Hume's (see HUME, D.).

A 'logic' in the broad sense of a methodology of knowledge, Crusius' *Weg* covers many topics treated by Wolff under empirical psychology. This is because philosophy was for him not merely a science of the possible but one dealing with really existing things. The general 'thinkability' (*cogitabilitas*) criterion that regulates it was therefore elaborated into three principles instead of one. To the formal principle of (A) non-contradiction from which Wolff had sought to derive all other truths (see Wolff, C. §6), Crusius thought it necessary to add two other, material principles: those of (B) inseparability (*das Nichtzutrennenden*) and (C) unconjoinability (*das Nichtzuverbindenden*). What can or cannot be conceptually separated or joined is not a question of logical possibility only but depends on the nature of the human understanding and the general content of experience. Accordingly Crusius also rejected Wolff's attempt to employ the mathematical method in philosophy, citing no less than nine differences between them, including the fact that mathematics begins with simple ideas whereas philosophy must discover them through an analysis of experience.

Like its counterpart, the will, the human understanding is composed of several basic powers, including sensation, reason, memory, and judgment. We have no clear grasp of these, nor of most other basic concepts, but know them only indirectly or relatively, through comparisons or their effects, in what Crusius calls symbolic as opposed to intuitive knowledge. Symbolic knowledge is regulated by principles (B) and (C) and can be (morally) certain even though it is incomplete. Its conclusions may not be ontologically valid and may, indeed, involve antinomic 'conflicting proofs', but this only reflects the fact that for Crusius some truths are not only beyond but even opposed to our limited human understanding.

Crusius' epistemology combines a Lockean doctrine of simple ideas, discovered through an analysis of experience, with a Leibnizian innatism prefiguring Kant (see Locke, J.; Kant, I. §§9-11). This becomes clearer in the *Entwurf*, which is sectioned into a reordered Wolffian scheme of ontology, theology, cosmology and pneumatology (rational psychology). Here Crusius discusses the (renamed) principle of determining reason, the distinction between the ideal (*ratio cognoscendi*) and the real (*ratio essendi vel fiendi*) ground of things, his doctrine of basic concepts (which he once called 'categories'), particularly space, time and causality, the failure of the ontological argument for God's existence, the nature and interaction of material and spiritual substances, and the two fundamental powers of the human soul, understanding and will.

The fact that the *Anweisung* was the first of Crusius' manuals to appear indicates the primacy of the practical in his thought. Its opening 'thelematology' discussing the human will and its component basic desires and essential freedom is followed by sections on ethics, natural moral theology, natural law, and prudence. These reflect both the standard natural law schema of duties to self, God and others, and the eudaimonist-perfectionist orientation of Leibniz and Wolff (see Natural law). What distinguishes Crusius is his integration of the intellectualist and voluntarist strains in ethics that had uneasily coexisted since Pufendorf into a form for which Kant has received most credit. Yet much of Kant's moral apparatus is Crusian, including the central notions of duty, obligation, law, right, virtue, happiness, the highest good, and the moral postulates (see KANT, I. §§9-11). Indeed, since Crusius clearly distinguished prudential and moral necessity, as well as action in accordance with and for the sake of duty, Kant's classification of him as a 'theological moralist' in the analytic of the *Critique of Practical Reason* (1788) is, while technically correct, also misleading. By not doing justice to Crusius it hides Kant's philosophical debts and thereby distorts the history of ethics.

3 Influence

Kant scholars rediscovered Crusius in the late nineteenth century. Yet even this relationship (most evident in Kant's *Reflexionen* of 1774-5 and lectures) is insufficiently understood, despite the seminal work of Heimsoeth (1956), Wundt (1964), Schmucker (1961) and Tonelli (1967, 1969). Crusius' influence on the *Nova Dilucidatio*

(1755) and the 'Prize Essay' (1764), where Kant distanced himself from Wolffianism, is clear, but his role in Kant's later theoretical and practical philosophy awaits more comprehensive assessment.

Little is known about Crusius' influence beyond Kant. He had numerous disciples into the 1770s, including A.F. Reinhard (1726-83), who received the 1755 Berlin Academy prize on the question of optimism. The Academy itself, led since 1745 by Maupertuis, had broad affinities with Crusianism because of its opposition to Leibniz and Wolff, but these too remain unelaborated. Other links requiring study are those with J.H. Lambert, M. Mendelssohn, J.B. Basedow (who shaped Kant's views on education), and Fichte, who knew Crusius through C.F. Pezold's important 1766 German edition of the *De usu* (see Fichte, J.G.).

Cudworth, Ralph (1617-88)

Ralph Cudworth was the leading philosopher of the group known as the Cambridge Platonists. In his lifetime he published only one work of philosophy, his True Intellectual System of the Universe (1678). This was intended as the first of a series of three volumes dealing with the general topic of liberty and necessity. Two further parts of this project were published posthumously, from the papers he left when he died: A Treatise Concerning Eternal and Immutable Morality (1731) and A Treatise of Freewill (1838).

Cudworth's so-called Cambridge Platonism is broadly Neoplatonic, but he was receptive to other currents of thought, both ancient and modern. In philosophy he was an antideterminist who strove to defend theism in rational terms, and to establish the certainty of knowledge and the existence of unchangeable moral principles in the face of the challenge of Hobbes and Spinoza. He admired and borrowed from Descartes, but also criticized aspects of Cartesianism.

Cudworth's starting point is his fundamental belief in the existence of God, conceived as a fully perfect being, infinitely powerful, wise and good. A major part of his True Intellectual System is taken up with the demonstration of the existence of God, largely through consensus gentium *(universal consent) arguments and the argument from design. The intellect behind his 'intellectual system' is the divine understanding. Mind is antecedent to the world, which is intelligible by virtue of the fact that it bears the stamp of its wise creator. The human mind is capable of knowing the world since it participates in the wisdom of God, whence epistemological certainty derives. The created world is also the best possible world, although not bound by necessity. A central element of Cudworth's philosophy is his defence of the freedom of will - a meaningful system of morals would be impossible without this freedom. Natural justice and morality are founded in the goodness and justice of God rather than in an arbitrary divine will. The principles of virtue and goodness, like the elements of truth, exist independently of human beings. A Treatise Concerning Eternal and Immutable Morality contains the most fully worked-out epistemology of any of the Cambridge Platonists and constitutes the most important statement of innate-idea epistemology by any British philosopher of the seventeenth century.*

1 Life

Cudworth was born in England at Aller, Somerset. Educated at Emmanuel College, Cambridge, he was elected to a fellowship in 1639. During the Civil War, in the wake of the Parliamentary purge of Cambridge dons, he was appointed Master of Clare Hall and Regius Professor of Hebrew. In 1654 he became master of Christ's College, a position which, along with the Regius Professorship, he retained at the restoration of the monarchy and occupied until his death. Cudworth was also one of the most learned classicists of his day. Although his religious background was in predestinarian Calvinism, he rejected his theological roots in favour of a more Arminian theology which stressed the role of reason in religion. This antivoluntarist stance went hand in hand with a tolerant outlook and an interest in millenarianism. He was consulted by Cromwell on the re-admission of the Jews to England.

Cudworth's philosophical antideterminism is the counterpart of his theological antivoluntarism. Common to both is his conception of the deity, which emphasizes divine goodness, wisdom and justice rather than the divine will. His antivoluntarism has fundamental philosophical implications. First, voluntarism leads to scepticism: if truth depends on God's arbitrary will, there can be no certainty. Second, if the will of God determined all human actions, then human beings would not be responsible for their actions and could not act morally. Furthermore, if the arbitrary will of God decided what was right and wrong, there could be no principles of morality. Voluntarism is the theological counterpart of the false intellectual systems of the philosophical determinists (see Voluntarism).

Cudworth was one of the first philosophers to write consistently in the English language. His philosophical reputation rests on a group of incomplete or posthumously-published treatises. The only philosophical work published in his lifetime was his *True Intellectual System of the Universe* (1678). This was originally conceived as part of a larger work on liberty and necessity, which he never completed. His posthumously published *Treatise Concerning Eternal and Immutable Morality* (1731) was originally intended as the epistemological prolegomenon to a projected treatise on ethics (never completed) of which *A Treatise of Free Will* (1838) was intended to form part. The latter prints one of three discussions of the subject which exist in manuscript. Both posthumously

published works of Cudworth as well as the unpublished writings develop philosophical themes sounded in his *True Intellectual System*.

2 *The True Intellectual System of the Universe*

The larger part of Cudworth's *True Intellectual System* is taken up with *consensus gentium* arguments for belief in a supreme deity. Cudworth marshals his immense classical erudition to demonstrate that belief in a deity is natural to humans, by showing that all humans at all times have had some kind of belief in a deity. Cudworth's survey of classical writings was also intended to vindicate corpuscularian natural philosophy from the charge of that it is intrinsically atheistic. Although Cudworth's *System* appears antiquarian, the arguments are relevant to the philosophy of his time and the whole work is underpinned by a concept of philosophy as a unified, timeless whole which has been the same since the beginning of time and which is concerned to discover the same single truth. This *philosophia perennis*, or perennial philosophy, derives from Renaissance models of the history of philosophy propounded by figures such as Agostino Steucho. It is dependent on syncretic and selective readings of philosophical texts, concentrating on noting parallels in doctrines rather than on analysing individual systems. On such a model, contemporary philosophy is not a new development but a recent manifestation of doctrines and arguments for which there are many analogues in antiquity.

For Cudworth, true philosophy is a combination of atomistic, mechanistic natural philosophy and a metaphysics concerned with the immortality of the soul and the existence of God. But this philosophy, originally propounded by Moses, has been corrupted over time. Cudworth distinguishes four distortions of the original atomism in four varieties of atheism: atomical atheism (according to which all things come about by chance), Hylozoic atheism (which imputes life to matter, associated with Strato of Lampsacus), Hylopathian atheism (which is merely materialistic, associated with Anaximander) and Cosmo-plastic atheism (which makes the world soul the highest *numen*). These schools of atheistic philosophy have their contemporary proponents: because he imputes the properties of spirit to matter, Spinoza is a Hylozoist, whereas Hobbes, by denying the existence of spirit, is a Hylopathian atheist.

Cudworth's taxonomy of atomistic philosophies is designed to distinguish between theistic and nontheistic forms of atomism. In this way he attempts to supply contemporary atomism with an impeccably theistic pedigree, clearing it of the imputation that all atomism is materialistic and therefore atheistic. True natural philosophy, he argues, leads inevitably to belief in God. Corpuscularian mechanism supports theism because it is impossible to explain movement, life or thought in terms of the properties attributed to material substance according to the mechanical philosophy, that is in terms of size, shape, position, motion and rest. Since these properties cannot by themselves account for 'Life and Cogitation, Sense and Consciousness, Reason and Understanding, Appetite and Will' (1678: 36), there must be some other cause, necessarily immaterial, namely a spirit or soul. Furthermore, the properties of matter may be deduced from the very idea of it. Matter is therefore intelligible without the useless and unintelligible scholastic apparatus of intentional species and substantial forms. In so far as Cudworth adopted the mechanical theory of matter, he was a modern in his natural philosophy.

3 Plastic Nature

In response to the shortcomings of the mechanical account of motion, Cudworth formulated his distinctive doctrine of Plastic Nature, a formative agency which acts as an intermediary between God and nature, maintaining the orderly day-to-day operations of the physical universe. The concept is indebted to the Platonic doctrine of *anima mundi*, and its functions are associated by Cudworth with the vegetable soul of Aristotelianism. Although he conceives of it as a spiritual agent, he insists that it operates unconsciously, performing the directives of God without question or foresight. Cudworth put forward his theory of Plastic Nature as an alternative to 'Fortuitous Mechanism' on the one hand, which explains all physical phenomena as the result of chance, and occasionalism, on the other, which requires God to intervene in even the most minute details of day-to-day natural occurrences (see Occasionalism). Occasionalist intervention is, in Cudworth's view, unbecoming to God, and it tends to atheism by undermining divine providence, rendering it 'operose, Sollicitous and Distractious'. Even when the mechanistic alternative to occasionalism admits the existence of a deity, it too tends towards atheism by reducing God to an 'idle Spectator'. The doctrine of Plastic Nature is thus designed to rescue divine providence. Its existence shows that nature is not the supreme *numen* but is subordinate to a Perfect Mind. Plastic Nature is the means whereby God imprints his presence on his creation, displaying his wisdom and goodness therein and

rendering it intelligible.

4 Epistemology

Contrary to what its title might suggest, *A Treatise Concerning Eternal and Immutable Morality* is largely a work of epistemology. Cudworth originally intended it to serve as prolegomenon to a work on ethics which he never completed, and of which *A Treatise of Freewill* constitutes a section on moral psychology. The fundamental ethical question posed in the overall work is that of Plato's *Euthyphro*: whether things are good because the gods will them, or whether the gods will them because they are good. The treatise is directed against the epistemology and moral relativism of Hobbes, though some of the discussion takes the form of a commentary on the views of Protagoras from Plato's *Theaetetus*. It is a fundamental tenet for Cudworth that moral values are really existing absolutes founded in the goodness and wisdom of God and that knowledge of moral principles is innate to the mind. He sets out the epistemological basis of this view by arguing that all intelligible things exist independently of human minds and even the world. Truth and the principles of knowledge are contained in the mind of God. Certain knowledge is possible because individual minds participate in the divine mind.

Cudworth's epistemology is constructed round the basic Platonic principles of archetype and ectype (form and copy): divine wisdom and knowledge is imprinted in individual minds as well as being reflected in the make-up of the physical world. Since knowledge is in this way innate to the mind, the process of cognition is an act of recollection. Here Cudworth employs the Platonic theory of *anamnesis*, as well as the Stoic concepts of *koinai ennoiai* (common notions) and *prolepsis* (anticipation) to develop the idea that the mind operates by a kind of foreknowledge or anticipation (see Plato §11; Stoicism §9). This a priori account of cognition accords with his fundamentally Platonic tenet that intellect precedes the world, ideas pre-exist things. But his theory of knowledge is not based on simple correspondence of ideas and things. Mind is not a passive receptor, but an active participant in cognition. Since truth is known from within the mind, not from without, sensory input is insufficient for understanding the external world. Sense data are received passively and piecemeal. Knowledge cannot be derived from them without a comprehending mind able apply 'conceptions or intelligible ideas' to sensory input. The mind focuses on the intelligible aspects of an object, the *scheses* or relationships between its parts, and so penetrates to its essence, understands its function. In the same way, the atomical philosophy can give a meaningful account of the nature of matter, undistracted by sense appearances. It is thus 'the triumph of reason over sense' because it 'solves all the phenomena of the corporeal world by those intelligible principles of magnitude, figure, site and motion, and thereby makes sensible things intelligible' (1731: 544).

5 Free will

In all probability Cudworth's unpublished writings on the subject of free will were a continuation of *Eternal and Immutable Morality*. The three surviving manuscripts on that subject overlap with one another in content, but none is complete (the first was printed in 1831, but the others contain important additions to the discussion). In these papers Cudworth argues that freedom of the will is an essential attribute of rational beings. Without free will moral responsibility would be impossible, and rational beings would be reduced to the level of mere machines. Cudworth conceives of free will as a 'ruling principle' or 'hegemonicon' of the soul which directs the actions of the individual being. More particularly, free will is a power of the soul which directs its actions towards the good. This conception of the beneficent partiality of the will leads Cudworth to repudiate any view that the will is indifferent. In so far as free will entails the power of furthering the perfection of a creature, it properly belongs only to beings capable of improvement. Consequently it is not an attribute of perfect beings and does not pertain to God. Furthermore, in so far as it may misdirect the soul towards spurious goods, it can lead to wrong doing. It is therefore, in Cudworth's phrase, 'a mungrell thing', since it combines the imperfection of the being to which it belongs and the perfection towards which that being aspires (see Free will; Will, the).

The soul is not constrained to act morally by external incentives or disincentives (such as rewards and punishments in the afterlife) but it contains within it the principles of virtue and vice, 'all moral habits' and conscience. This internal moral sense of the soul is superior to intellection and a token of the presence of the divine. Error is a consequence of the imperfection of created beings, who cannot always see the truth clearly and consequently often make judgments about action without clearly and distinctly perceiving the truth.

Cudworth's concept of free will is sustained by a unitary concept of the soul and its powers. The soul is a single,

uncompartmentalized unity, compounded of powers or principles, two higher and one lower. It is the function of the middle principle, or free will, to control the lower appetites and to direct the soul towards the highest principle, the *summum bonum*, just as the charioteer in Plato's *Phaedrus* controls the contrary impulses of his two horses to make them pull in the same direction. The term Cudworth uses to describe the exercise of the power of the controlling principle is 'conatus' (striving).

Cudworth's emphasis on the unitary function of the will, and its integration with the soul as a whole, enables him to side-step what he sees as the irresolvable dilemma of philosophers about the priority of reason over will, or will over reason. Furthermore, the integrative function of his 'middle' principle makes it possible to explain close interaction of mind and body, since the domain of the middle principle extends both to the lower, animal appetites and to the higher principles of the soul. In this respect his conception of free will enables him to avoid the problems associated with Cartesian dualism of mind and body (see Dualism).

6 Relation to Descartes

Cudworth kept abreast of contemporary developments in philosophy and in what we now call science. Indeed, he regarded his 'intellectual system' as the counterpart in philosophy of the physical world system of Copernicus and Galileo. Cudworth was a perceptive critic of contemporary philosophy. His negative assessment of Hobbes and Spinoza was related to his critique of determinism and materialism. His relationship to Descartes was more complex: his philosophy is indebted to Cartesianism in many fundamentals, but he was also critical of Descartes in important particulars. He took over Cartesian dualism of mind and body, and drew on Descartes' theory of the passions. He incorporated the Cartesian account of body into his own philosophy (regarding Descartes as a reviver of Democritean atomism). In epistemology he adopted the Cartesian principle of 'Clear Perceptibility or Intelligibility' as the criterion of truth and used it to underwrite his Platonist identification of being with truth: 'whatsoever is clearly and distinctly perceived to *Be, Is*'. None the less Cudworth put forward a number of criticisms of Descartes, all with sceptical implications. In his *System* (I.iv) he argues that Descartes' proof of the existence of God in the *Meditations* is circular - Descartes first employs the faculties of reason and understanding to prove that God exists, and then proves the truth of those faculties from the existence of God. The argument for the existence of God from the idea of necessary existence, is fallacious because it draws an absolute conclusion from a mere hypothesis. Cudworth offers a number of amendments to Descartes' arguments in an attempt to strengthen them (for example, replacing the argument from necessary existence by one based on possible existence). His other criticisms of Cartesianism are theological, though with important philosophical implications. He argues that Descartes' voluntarism leads to scepticism and his denial of final causes undermines providence. On both these counts Cartesianism is potentially atheistic and Descartes has not been true to his own principles (see Descartes, R. §6).

7 Influence

The weighty humanist erudition which encumbers *The True Intellectual System* is largely responsible for the fact that Cudworth is less well known than he deserves to be. But his philosophy continued to arouse interest in both Britain and the rest of Europe during the last part of the seventeenth and throughout the eighteenth centuries. Cudworth's British legacy remains to be charted in detail, but mention should be made of John Ray, Locke (his critique of innate ideas notwithstanding), Shaftesbury, Ramsay, Price and Reid. Thomas Wise produced a severely pruned edition of *The True Intellectual System* in 1703, designed to focus on theological issues of the early eighteenth century. *A Treatise Concerning Eternal and Immutable Morality* was published by Edward Chandler during the course of the eighteenth-century debate on ethical rationalism sparked by criticisms of Samuel Clarke. Thanks to J.L. Mosheim's Latin translation (1733), Cudworth's writings were known in Germany in the time of Kant. Through extracts published by Jean Le Clerc in the *Bibliothèque choisie* (1703-6), and the controversy between Le Clerc and Bayle which ensued, aspects of Cudworth's philosophy (especially his theory of Plastic Nature) entered enlightenment debates. The doctrine of Plastic Nature was defended by Paul Janet in France as late as the nineteenth-century (Simonutti 1993); and in 1823, Cudworth's philosophy was translated into Italian by Luigi Benedetti.

Cultural identity

If cultural identity means that a person achieves the fullest humanity within an accepted context of traditional symbols, judgments, values, behaviour and relationships with specific others who self-consciously think of themselves as a community, then it must be seen as a great contemporary challenge to many Western philosophical assertions about the person, society, meaning and truth.

This sense of cultural identity, as well as more extreme forms, can amount to classic determinism: individuals are subsumed under the relations with meaning and people surrounding them. Advocates of the centrality of cultural identity often make an argument rooted in an 'authenticity' which purports that, to fully encounter oneself, each of us must grasp and fully accept one's psychological and social location within a specific group of people who interpret life in terms of the particular civilization that contains them.

1 Philosophy and cultural identity

In the twentieth century Western philosophy has endured many assaults on the claims of some of its practitioners that it somehow constitutes a foundational discipline whose concerns are basic to any comprehensive analysis of what it means to be human. In some intellectual quarters the most formidable challenges arise from both scientific practice and the dominant models and images therein. This view is often found among analytic philosophers trained in the Anglo-American traditions. These traditions have emphasized the close study of 'linguistic claims' and sentences whose truth these philosophers seek to ascertain by appealing to logic and 'common language usage'.

Usually quite separate from that tradition have been other continental ones whose fundamental texts were first written in German, French, or more rarely for English-speaking students of philosophy, Russian, Italian, or Spanish. At least some of these European advocates have been influenced by Friedrich Nietzsche and other thinkers (including those commonly called philosophers but also literary figures, artists and social theorists) of an intellectual tradition descended from Nietzsche.

From such a Nietzschean perspective, concepts like cultural identity pose problems of the range and possibility of philosophy quite different from those of science. The Spanish thinker José Ortega Y Gasset has described himself as a human creature who is both 'myself and my circumstance'. In that duality Ortega Y Gasset demonstrates what it means to have become aware of context, or what some existentialists have called 'situationality'. Even when people think it is better to seek truth, they still exist within a situation of having been influenced both consciously and unconsciously by their circumstances in the world.

Thus issues of cultural identity can cause a crisis of legitimacy for any human activity which stresses the search for basic truths, fundamental realities and those thoughts or ideas which serve to ground our lives. If we are creatures with identities rooted in specific cultures, then the ancient Western idealist sense of the humanly universal is either suspect or defunct. This might be because we become products of cultural contexts so that we and the people we encounter across the world may be more fundamentally different than similar.

2 Community and belonging

The decline of empires in the twentieth century has contributed to new senses of this issue of the problematic commonality of individuals and societies. In recent centuries imperial Europeans, the people of the USA, as well as the Japanese, Chinese, Russian, Turkish, Incan, Aztec and various dominant tribes in other continents could confidently view other peoples as still being in need of protection, advancement, development and civilizing enlightenment. Late in this century in numerous areas of the world, the question of what it is to be fully human has arisen, with the conclusion that individuals must define themselves in terms native to the people or community to which they belong. Put radically, 'belonging' within such theories of cultural identity becomes the first condition for achieving full adulthood for members of our species. It is only when we acknowledge to which group we belong that we can discover who we are and what being human truly means.

This perspective has the effect of making most intellectual activity regional. Our symbols and their meaning essentially become products of those others who collectively give us our neighbouring human groups. This is a

process connected to psychology in personal and social senses: adult consciousness is a result of belonging to a group, or community. Self-image necessarily evolved from and continues to comprise elements derived from our personal situations in tandem with others.

Politically this appeal to the region of nearby others and their established meanings for our selfhood has the effect of determining to what group we belong within other neighbourhoods of the world and thus where else we can expect both to be welcome and express the best of ourselves. Such perspectives permit cultural identity to provide people both like and unlike ourselves with the certainty of boundaries. From a psychosocial position, these perspectives of cultural identity can be seen as safe and 'authentic', however, they can also be anti-cosmopolitan, anti-individualistic and relativistic. Their appeal may be seen on two levels: for the relatively powerless there is the possibility of successful initiation and nurture within a tradition of relations and symbolic expression; for the powerful within such a self-defining community there is a means to unify the group and establish both its continuity of power and ready-made 'outsiders' to serve whatever purposes might sustain that power as well as the group's position among other groups.

In the West, within the great democracies and among the ruins of the old empires, appeals to cultural identity have tended to be voiced in three ways. Some groups have insisted on the inevitable alienation their members experience when left as unintegrated, unhappy, unfulfilled, though nominal citizens of such states as the former Soviet Union, Eastern Europe and China. In countries like the USA, Canada, many European countries and other technologically advanced nations like Australia, New Zealand and Japan, some have demanded that the dominant culture admit the presence of and provide significant resources for (sometimes as restitution for past suppressions) groups either fully in possession of their cultural inheritances or struggling before the indifference or hostility of some members of dominant groups. Finally, in some developing nations a combination of two other tendencies has arisen: some communities or peoples wish to escape traditional control by the central metropolitan powers, while others want a better deal from those powers as they continue to be valued components of the nation. This mix can be found in countries such as India, Brazil, Mexico, Malaysia, Indonesia, the Philippines, Nigeria and Zaïre.

In terms of such topics, discussions of cultural identity are difficult to find outside issues arising from the remnants of empire and the countervailing gestures of liberation. In the context of theories of liberation from the old empires, some religious movements seem deeply committed to advancing accompanying cultural identities. Variants of Islam fit this model, as do evangelical Protestants in Catholic countries in Latin America.

More controversially, in the most developed areas of the world cultural identity has sometimes been transformed into a self-defining paradigm for the liberation of women, gays and lesbians. In these cases some have argued that a mix of roles, attitudes, values, personalities, interpersonal styles, language patterns, behaviour, ethics and other expressions constitute a separate origin for identity that is parallel in form to and more powerful than more traditional concepts such as ethnicity or race. From such perspectives being feminist or gay conveys a centrality or origin of personhood that is foundational to personal identity, which manifests itself coincidentally in what these theorists call a separate culture.

However, determinisms tend to crowd and frustrate people when the search for a fundamental essence becomes serious. Most advocates of personhood which focuses on cultural identity do not want to accept gender or sexual preference as competing forms of personal identity. Their usual position is to stress how these aspects of humanity bear out the evidence of the effects of particular cultures, or subcultures within larger social units like nation states and thus provide arenas within behaviour for seeing the power and separateness of cultural identity. Instead of stressing common forms of the feminine, such advocates choose to emphasize the differences of women's roles from one community to another.

Cultural identity, in its purer forms, should be seen as an assertion of an essentialist argument: we are what those among whom we have been raised have made us. We cannot find ourselves fully without embracing these community-based relations: from them we get a sense of what is important and definitional about our lives.

3 Alternative perspectives

There are at least three alternatives which oppose such notions: first, advocates of human generality, often expressed as 'universal humanity', stress intuitions and evidence that common structures arise routinely within the lives of people supposedly living within other, sometimes 'opposed' cultures. From such a perspective, placing a

stress on polarized cultural identities is tangential, narrow and by definition dehumanizing and thus dangerous. Second, cultural identity is a stance rooted more in the politics of the decline of empires than in anything foundational. The reservations inscribed in this stance might be that advocates of cultural identity practise a form of 'local politics' whereby they seek to take advantage of guilt arising from the legacy of empires and stigmatized hegemonic attitudes. This criticism emphasizes the political and social advantages accrued by the leaders of movements who wish to be compensated for past gestures directed at the affected group by dominant cultures and societies. The third opposition to previously discussed notions of community and belonging is that we are individuals whose lives are particularized by the accidents of space, time, biology and history in ways which are unique. Within the terms of this model, cultural origins are extremely important, but they themselves can become critical topics: their elements can become other for us and can be altered or disowned. Options from other human cultures can be substituted or adopted by us.

Culture

Culture comprises those aspects of human activity which are socially rather than genetically transmitted. Each social group is characterized by its own culture, which informs the thought and activity of its members in myriad ways, perceptible and imperceptible. The notion of culture, as an explanatory concept, gained prominence at the end of the eighteenth century, as a reaction against the Enlightenment's belief in the unity of mankind and universal progress. According to J.G. Herder, each culture is different and has its own systems of meaning and value, and cannot be ranked on any universal scale. Followers of Herder, such as Nietzsche and Spengler, stressed the organic nature of culture and praised cultural particularity against what Spengler called civilization, the world city in which cultural distinctions are eroded. It is difficult, however, to see how Herder and his followers avoid an ultimately self-defeating cultural relativism; the task of those who understand the significance of human culture is to make sense of it without sealing cultures off from one another and making interplay between them impossible.

Over and above the anthropological sense of culture, there is also the sense of culture as that through which a people's highest spiritual and artistic aspirations are articulated. Culture in this sense has been seen by Matthew Arnold and others as a substitute for religion, or as a kind of secular religion. While culture in this sense can certainly inveigh against materialism, it is less clear that it can do this effectively without a basis in religion. Nor is it clear that a rigid distinction between high and low culture is desirable. It is, in fact, only the artistic modernists of the twentieth century who have articulated such a distinction in their work, to the detriment of the high and the low culture of our time.

1 Definition of culture

In human history, culture in its broadest sense is that which is socially rather than genetically transmitted. It is that which children learn by virtue of their being brought up in one group rather than another, and, in its totality, it is that which distinguishes one human group from another. To human culture belong language, customs, morality, types of economy and technology, art and architecture, modes of entertainment, legal systems, religion, systems of education and upbringing, and much else besides; everything, in other words, by virtue of which members of a group endow their activities with meaning and significance. Even from the brief list of elements comprising a culture, it will be evident that there is no clear criterion for identity in the case of human culture. Cultures are characteristically permeable, evolving, open to influence from outside and inside in unpredictable ways, liable to be divided into subcultures, and to generate offspring with their own lives and development. And while individuals from a given culture are formed by it in all sorts of ways, conscious and unconscious, theoretical and practical, individuals are not prisoners within their cultures, but can affect them, react against them and contribute to their development.

2 Herder and the centrality of culture

In view of the all-encompassing nature of culture and of the multiple vaguenesses connected with the notion, one might be tempted to wonder whether it is a useful concept at all. That it is not just useful, but central to the analysis of history, was strongly urged by Herder (§4) in a sustained onslaught on Enlightenment thinking. Against the Enlightenment's conception of the unity of mankind and its belief in progress, Herder stressed the plurality of human societies and the incommensurability of their values (and hence the impossibility of talking of historical progress in any uncontested way). According to Herder, each of us is what we are because of the group to which we belong. Activity and self-expression are valuable in the degree to which they express the personality of the individual agent and that of the group to which they belong. Stressing the organic nature of human societies and the interplay between societies and cultures, Herder rejects centralization, bureaucracy, the elimination of cultural diversity and, above all, imperialism. In his *Briefe zur Beförderung der Humanität (Letters for the Advancement of Mankind)*, he asks:

> Can you name a land where Europeans have entered without defiling themselves forever before defenceless, trusting mankind? …Our part of the earth should not be called the wisest, but the most arrogant, aggressive, money-minded: what it has given these peoples (the colonies) is not civilization but the destruction of the rudiments of their own cultures wherever they could achieve this.

(Herder, quoted in Berlin 1976: 160-1)

The world in which each of us lives is a particular cultural inheritance, binding us to our forefathers and to our descendants, and distinguishing us from members of other cultures. Herder is clearly right to make what is, in effect, the distinction between causal explanations and explanations in terms of meaning. Human beings are not machines, and our activities cannot be accounted for in terms of scientific psychology; while we doubtless have animal needs and urges, our lives are lived for the most part in realms of meaning, even in pursuit of such elementary needs as food, shelter and sex. The human *Lebenswelt* is a world of *intelligibilia*, of norms and normativity, of activities regulated by standards and fashions and criteria demanding our allegiance, on pain of lapse into brutishness, outlawry and, ultimately, incoherence.

If Herder had done no more than draw attention to the importance of culture and meaning in human affairs, and to the equivocal nature of the concept of progress, there would be few who would dissent. His position, however, becomes more problematic when wrestling with the consequences he derives from it. Thus, Herder's dislike of nationalism and repudiation of the idea of a *Favoritvolk* leads him into a cultural relativism which has at least as many difficulties as the nationalist supremacism of successors such as Fichte (see Nation and Nationalism). At the same time, his insistence on the organic nature of culture and his rejection of cosmopolitanism (even if in the form of imperialism) may well have provided encouragement to the very nationalism he deplored. Certainly, it is hard not to see Spengler's celebrated distinction between civilization and culture as owing as much to Herder as to Nietzsche (who was himself no mean exponent of cultural essences). For Spengler, the very idea of a cosmopolis, a world city, is a symptom of decline from the higher state of culture.

3 Culture and civilization

For Spengler (who is in his own way elaborating themes from Nietzsche's *The Birth of Tragedy*), civilization is the movement away from the strong local and unquestioned bonds which constitute organic culture:

> In place of a type-true people, born of and grown on the soil, there is a new type of nomad, cohering unstably in fluid masses, the parasitical city-dweller, traditionless, utterly matter-of-fact, religionless, clever, unfaithful, deeply contemptuous of the countryman, and especially that highest form of countryman, the country gentleman.

(Spengler [1917-22] 1926-8: 32)

Along with the decline of organic culture comes science, rationalism, socialism, internationalism, a preoccupation with trade and luxury, wage disputes and football grounds; all, in other words, which is characteristic of modernity. Like Herder, Spengler does not see any of this as progress, although one wonders whether the deep-seated relativism to which both are committed entitles them to see it as decline either.

4 Cultural relativism

Cultural relativism, indeed, is the pathos of strong theories of culture. What in the hands of Herder and Spengler began as a reasonable reaction against the facile optimism and scientism of the Enlightenment and its offshoots, such as socialism and utilitarianism, can turn all too quickly into an enervating and disabling relativism. This relativism deprives itself of the resources to criticize barbaric societies, old and new. It is noteworthy that for all his invective against both Rome and what he calls its lack of soul, and against the twentieth-century world, Spengler is carefully even-handed in praising the Colosseum and 'the brown massiveness' of Roman brickwork, as well as the aero-engines, the precision lathes and the steel structures of his own day (Spengler 1917-22: introduction). Moreover, there is a worrying determinism in making culture too definitive of the group to which it belongs, in that any reception of outside influence is going to seem either impossible in appealing to values not recognized by insiders or undesirable in diluting the purity and distinctiveness of a culture; or, at different times, both before and after it has happened.

While with regard to culture neither Herder nor Spengler avoid the traps laid by relativism, determinism and prescriptivism, no important thinker who has seen the significance of culture has shown clearly how attendant dangers are to be avoided without lapsing into a kind of universalism which cannot accommodate any significant understanding of culture (see Relativism; Social relativism).

5 Common culture and high culture

So far, this entry has focused on what might be called the anthropological sense of culture: that memorably described by T.S. Eliot as involving all the characteristic activities and interests of a people (Eliot 1948). Speaking of English culture, Eliot lists Derby Day, Henley Regatta, Cowes, the Twelfth of August, a cup final, the dog races, the pin-table, the dartboard, Wensleydale cheese, boiled cabbage cut into sections, beetroot in vinegar, nineteenth-century Gothic churches and the music of Elgar. Eliot, being an American, was rather better positioned to describe *English* culture than most Englishmen. So much of a culture is traditional, unspoken, taken for granted, even unrealized by its adherents. It nevertheless gives form and meaning and moral direction to the experience of those who belong to it. It is partly because of its tacit dimension that theorists of culture fear that too much explicitness, too much reasoning and too much change will unbalance the common culture of a people, and so change or even subvert its identity. Why is the cabbage cut into sections? Isn't Wensleydale cheese hard to make conform to Euro-standards? Shouldn't the cup final be played so as to fit the demands of television? After not very much of this, the whole world, or so it seems, starts to dance to the tune of McDonald's and satellite TV.

After giving his list, Eliot goes on to enunciate what he calls 'the strange idea that what is part of our culture is also part of our *lived* religion' (Eliot [1948] 1962: 31; original emphasis). Eliot's own idea was that a people's culture is the incarnation of its religion, although as he concedes that materialism could be a religion in the required sense, it is hard to assess the force of this claim.

More characteristic of thinking about culture over the last 200 years is the claim associated first with Schiller and, in the English-speaking world, with Carlyle, Ruskin, Matthew Arnold and F.R. Leavis; namely, that culture or, more precisely, high culture can somehow substitute for religions. The thought is that in the absence of an acceptable dogmatic religion, people's highest aspirations and spiritual life are best expressed in works of art.

Leavis' continual complaint was that in so much of contemporary life we find 'no goals having any real authority except those capable of measurement' (Leavis 1972). In such circumstances, we lose our sense of the value and meaning and potential of life; there is 'no wealth, but life', as Ruskin put it, but we no longer have any sure sense of what wealth in life is, or how life should be lived to mine its wealth. The thought is that in some works of art, (in Leavis' view, such as in Eliot's poetry, in D.H. Lawrence and in Blake), we are brought up short against a harder reality than we normally encounter in the utilitarian, hedonistic, calculating world in which we spend most of our lives, and we glimpse possibilities of something higher or deeper.

Certainly Beethoven's symphonies and quartets, the painting of Turner and Van Gogh, the poetry of Rilke and the writing of Proust, are for many today epiphanic or revelatory in the way religion once was. Artists of this calibre seem to Leavis to form a league against the philistine, Benthamite world (which includes among its characteristic products most contemporary analytical philosophy). And art, in this highest sense, spreads messages more terrifying than the insipid 'sweetness and light' which Arnold thought could form a bulwark against anarchy.

It must, however, be a moot point as to whether any of the exponents of the arts mentioned above would have seen themselves as unreligious or in competition with religion as such, rather than as hostile to some very specific forms of religion. It is, in other words, a moot point as to whether art can uplift in the way Leavis and the other critics hope if all doors are closed against religious hope, or whether an explicitly humanistic, atheistical art would not be likely simply to reinforce the very materialism Leavis hopes literature will rebut.

Whether high culture can perform the role foisted on it or not, the very notion of a high culture is increasingly questioned, not least by contemporary artists and critics themselves. Eliot argued that hereditary class divisions were essential for a healthy culture and a healthy art, and however romantically we may look at the groundlings in Shakespeare's theatre or the whole city enraptured by Aeschylus, it is undeniable that there are elements in Shakespeare and Aeschylus which repay and demand the highest levels of attention, ability and concentration, levels clearly beyond the majority of any population known in history.

What, however, is not in doubt is that there have been times and places in which the majority of a culture have been capable of responding in some way to Aeschylus and Shakespeare; as also to Raphael or Rembrandt or Mozart or to the Authorized Version of the Bible. In the same way, 'high' artists, such as Bach, Schubert, Scott, Dickens, Hogarth and David, have drawn on popular forms and created popular forms themselves. The truth is that at least until this century, culture and art have operated at different levels, but in a way in which there were

continuities and overlaps. It is only with the giants of twentieth-century modernism - Schoenberg, Le Corbusier and, to a lesser degree, Picasso and Braque - that exponents of high culture have deliberately cut themselves off from their roots in the surrounding popular culture. The result has been a hermetic and self-referential high culture lacking popular appeal, and a popular culture with few values other than those of advertising and the mass media. The conclusion prompted by this observation is that in cultural matters, the important distinction is not so much that between high culture and popular culture as that between good cultural times and bad cultural times; and that just as good works can be found at both the high and the popular ends of the spectrum, so in bad times works low in ambition and achievement can be found in prestigious galleries and concert halls just as much as in the mass media.

Culverwell, Nathaniel (*c*.1618-*c*.1651)

Nathaniel Culverwell (or Culverwel) was one of the first natural law theorists in seventeenth-century England, and one of the first moral philosophers to stress the primacy of reason. His aim was to revive the natural law tradition of Aquinas and Suarez, which had fallen into disrepute in English Calvinism. Culverwell's theory is a synthesis of rationalism and voluntarism. It attempts to do justice to both the normative and coercive, to the moral and punitive aspects of law. The emphasis of his theory is, however, strongly rationalist, a reaction against the voluntarist legacy of Calvinism. Culverwell had close connections with some of the leading figures of Cambridge Platonism. He is not, however, a typical member of this school, because of the strong Calvinist strands of his early sermons.

1 Life and work

Not much is known about Nathaniel Culverwell's life. Born into a prominent family of Puritan clergymen, he was christened on 13 January 1619. In 1633 he was admitted to Emmanuel College, Cambridge, where he took his B.A. in 1636 and his M.A. in 1640. Emmanuel College was then notorious as a 'Puritan nursery', but it was also the cradle of Cambridge Platonism (see Cambridge Platonism). Among Culverwell's fellow undergraduates were Ralph Cudworth, John Smith and John Worthington, and it is probable that Culverwell's tutor was Benjamin Whichcote. Culverwell was made a Fellow of Emmanuel in 1642. He died young, probably in 1651.

Culverwell published nothing in his lifetime. His most important work is *An Elegant and Learned Discourse of the Light of Nature* (1652), edited by his colleague William Dillingham. This work was probably written during the university year 1645-6, when it was delivered as a series of sermons in Emmanuel College chapel. Culverwell also wrote eight sermons, which were published with the *Discourse*. The most important of these are 'The White Stone', whose theme is the need to make our election sure, and 'Spiritual Opticks', whose subject is the imperfection of our knowledge of God in this life.

2 Natural law

Culverwell's *Discourse* occupies an important place in the history of English moral philosophy. Appearing before the ethical works of Richard Cumberland, John Locke, Jeremy Taylor, Ralph Cudworth and Henry More, it is one of the first attempts in English Protestantism to stress the role of reason in ethics and to develop a doctrine of natural law. Like Richard Hooker, Culverwell wanted to revive the natural law tradition of Aquinas and Suarez, and to combat the nominalist legacy of Protestantism, which had reduced natural law to divine commands (see Aquinas, T. §13; Cudworth, R. §§4-5; Locke, J. §9; Suarez, F. §4).

The general purpose of the *Discourse* was to determine the proper relationship between reason and faith. Culverwell attempted to strike a middle path between the Socinians, who praised reason at the expense of faith (see Socinianism), and the radical sects, who demoted reason for the sake of the gospel. He maintained that although reason cannot discover or demonstrate the essential mysteries of the gospel - the Trinity, Incarnation and salvation - it can determine the law of nature, which is a reflection of the eternal law of God. Although Culverwell aimed at a *via media*, his chief goal was to defend the powers of reason. He wrote mainly to combat the rise of antinomian sects which taught that all moral laws had been abrogated by the gospel. Their teaching not only posed the dangers of immoralism and anarchism, but it also impugned Calvinism itself, which always stressed the role of grace over reason. In introducing natural law into Calvinism, then, Culverwell's intention was to clear it of the charge of antinomianism (see Calvin, J.).

The basics of Culverwell's doctrine of natural law closely follow Aquinas and Suarez. Like Aquinas, Culverwell holds that the law of nature is the participation of our reason in the eternal law of God. And, true to Suarez, Culverwell argues that the law of nature is essential to a rational being, and cannot apply to animals or nature in general, for 'where there is no Liberty, there's no Law, a Law being nothing else, but a Rational restraint, and limitation of absolute Liberty'. Although he admired the modern natural law theorists John Selden, Hugo Grotius and Claudius Salmasius, Culverwell criticized them because they presupposed but did not examine the general concept of nature. In explaining this concept, Culverwell again returned to the scholastic tradition, defining the nature of a thing as its essence, its characteristic manner of acting.

Although he has been described as a 'voluntarist', Culverwell attempts to avoid the extremes of both voluntarism

and rationalism (see Voluntarism; Rationalism). The foundation of his position is the scholastic distinction between the normative and coercive, or demonstrative and preceptive aspects of law. The normative or demonstrative aspect is its moral justification, the reasons for acting according to it; the coercive or preceptive aspect is the will that decrees it and the power that enforces it. Again following Aquinas and Suarez, Culverwell maintains that both these elements are necessary to an adequate concept of the law of nature. On the one hand, like all laws, the law of nature involves an act of will, a power of enforcement; hence, contrary to rationalism, there could not be a law of nature if God did not exist. On the other hand, the law of nature has a moral validity, a ground of obligation, independent of the will; contrary to voluntarism, then, nothing is right or wrong simply because God commands it. Although Culverwell stresses the importance of the divine will as the source of law, the emphasis of his theory is on reason, which had been underrated in the voluntarist tradition of Calvinism.

For Culverwell, the foundation of the law of nature rests upon the innate faculties of man, which express themselves in self-evident principles such as ‘do unto others as you would have them do unto you’. Culverwell denies, however, that we have pre-existing ideas and argues that only our faculties are innate. Unlike the Cambridge Platonists, he stresses that knowledge requires experience as much as the activity of reason.

3 Cambridge Platonism

Culverwell’s position within Cambridge Platonism has been the subject of dispute. Some regard him as a paradigmatic Platonist, while others place him outside this movement because of his Calvinism. Undoubtedly, there are deeper strains of Calvinism in Culverwell than in most of the Cambridge Platonists, so that it is misleading to regard him as typical of the movement. Some of the early sermons, especially ‘The Act of Oblivion’, ‘The White Stone’ and ‘Spiritual Opticks’, stress some standard Calvinist doctrines: predestination, the necessity of grace, the distinction between the elect and reprobate, and the inadequacy of human reason to understand salvation. These were doctrines that were decisively rejected by Whichcote, Cudworth and More in the 1640s. On the other hand, it is important to recognize that, in the 1640s, many of the rationalist strands of Cambridge Platonism were still only nascent. There are indeed strong Calvinist remnants in Whichcote, Cudworth and More, who stress the necessity of grace no less than Culverwell. Any sharp distinction between Culverwell and Cambridge Platonism therefore runs the risk of anachronism, reading the early years of Cambridge Platonism in the light of its later doctrines. The distinction becomes sharp only by overrating the rationalist strands, and underrating the Calvinist ones, in Cambridge Platonism.

It is more accurate to regard Culverwell as a transitional figure between Calvinism and Cambridge Platonism. It is also likely that Culverwell’s doctrines were in evolution, moving away from Calvinism and towards a greater rationalism, since there is a greater emphasis upon the value of reason in the *Discourse* than in the earlier sermons. It is a sad fact that, given his early death, we can only speculate about the final result of Culverwell’s intellectual development.

Cumberland, Richard (1632-1718)

Richard Cumberland developed his ideas in response to Hobbes' Leviathan. He introduced concepts of aggregate goodness (later used in utilitarianism), of benevolence (used in moral-sense theory), of moral self-obligation, of empirical proofs of providence and of the moral importance of tradition à lá Burke. The philosophical basis for Cumberland's views was a theory of natural law which was strongly anti-voluntarist and committed to objective moral values, but recognizing institutions such as governments of state and church as conventional or traditional. Cumberland was often seen as the third co-founder, with Pufendorf and Grotius, of modern natural law.

The English philosopher Richard Cumberland was educated at Magdalene College, Cambridge, and in several respects was close to the Cambridge Platonists as well as to Nathaniel Culverwell (see Cambridge Platonism). He subscribed to an extreme Erastianism that saw him through both the Restoration of 1660 and the Revolution of 1688-9. He was in fact on the far latitudinarian wing of the Anglican Church, and it is fitting that he was made Bishop of Peterborough as part of the Revolution settlement in 1691. His only philosophical work, *De legibus naturae*, appeared in 1672, the same year as Pufendorf's *De iure naturae et gentium* (see Pufendorf, S.). His other works were in such areas as patriarchal law, Jewish weights and measures, and Phoenician history.

The primary objective of Cumberland's philosophical work was to refute Hobbes by showing that morals has an objective basis and that it cannot simply be the imposition of a sovereign power (see Hobbes, T. §5). This objective basis is to be found in the common good, by which he means the good of the universal moral community of God and humanity through all times. By promoting this common good, we will inevitably promote our own good, but we in fact have a natural inclination (an active power) to pursue the common good, namely benevolence. This natural inclination can be regulated by reason through precepts.

Once we learn through experience, systematized in the science of morals, that benevolence is universal and thus part of God's will, we will realize that the rational precepts which we have developed are, in fact, natural laws prescribed by God; we will see that the natural inclinations to benevolence are also moral virtues; and we will understand that the common good is not just a natural good but a moral good .

Behind all this lies the common idea that morality is a matter of obligation to the law of a superior. Yet, Cumberland avoids a voluntarist view of law and obligation (see Voluntarism). God himself wills as law what is for the common good, but he obliges humanity to obey the law, not by his mere willing it nor by an appeal to the human rational calculation of pleasures and pains, but by an invitation to unify each person's particular will with the general will of God. God is the perfect intuitionist utilitarian who alone is capable of self-obligation, and humans can imperfectly take part in his unity of intuition and will. God's invitation to humanity - revelation apart - is expressed in the rewards and punishments that are naturally connected with compliance with, and transgression of, the law of nature. These are not, as a common utilitarian reading will have it, sanctions for or grounds of obligation to the law of nature; they are grounds of discovery of the law of nature (see Utilitarianism).

While his language is often vague, Cumberland clearly eschews hedonism as an account of the good, including the common good (see Hedonism). He seems to be aiming at a notion of self-perfection as the ideal good, but the perfection in question is, in turn, formalistically understood. It consists in an approximation to the general will of God which, if achieved, would establish a harmonious system of all the individuals making up the moral universe. Like his contemporary, Malebranche, but independently of him, Cumberland is thus coming close to a notion of universalizability (see Malebranche, N. §§5-6).

Cumberland's idea of the harmonious moral system of mutually interdependent individuals was a conscious attempt to transfer Descartes' theory of the full physical world, or *plenum*, to morals. It contributed to the subsequent age's development of an empirical science of morals and thus to the breach with Locke's idea of morals as a demonstrative science (see Descartes, R. §11; Locke, J. §9). The science of morals he regarded as a system of cohering individuals, but the mechanisms that made them cohere were a matter of empirical investigation. Cumberland thus joined Locke in rejecting innate ideas. But one of the empirical factors in accounting for the mind was teleological, namely the mind's possible understanding of, and associated striving for, the common good. By accounting for the universal moral system as a possibility, moral science acquired a

normative function. This role of moral science as self-fulfilling prediction, while rudimentary in Cumberland, became a lasting feature of British moral thought for more than a century.

As with so many natural lawyers, Cumberland has no strong theory of contract. The duties undertaken in contractual relations are, in so far as they are just, nothing but duties imposed by natural law, and rights are simply derivative from the duties. Contracts thus function only to make explicit what is implied by natural law. What is more, Cumberland is keen to acknowledge historically-given moral institutions. In language that often is strikingly Burkean, he maintains that such given institutions provide the best contribution to the common good simply because of the losses to be expected from major reform. Hand in hand with this, he points out that natural benevolence tends to establish social relations, including economic ones, that are independent of political society. When Dugald Stewart, early in the nineteenth century, maintained that Cumberland was an inspiration for the Scottish school of moral thought in the intervening century, he thus had a strong point.

Cynics

Cynicism (originating in the mid-fourth century BC*) was arguably the most original and influential branch of the Socratic tradition in antiquity, whether we consider its impact on the formation of Stoicism or its role in the Roman Empire as a popular philosophy and literary tradition. The self-imposed nickname 'Cynic', literally 'doglike', was originally applied to Antisthenes and to Diogenes of Sinope, considered the founders of Cynicism, and later to their followers, including Crates of Thebes and Menippus. It emphasizes one of the most fundamental and controversial features of Cynic thought and practice - its radical re-examination of the animal nature of the human being. Their decision to 'play the dog' revolutionized moral discourse, since humans had traditionally been defined by their place in both a natural (animal → human → god) and a civic hierarchy. By calling such hierarchies into question, Cynicism re-evaluated the place of humankind in nature and the role of civilization in human life.*

*Cynicism includes an innovative and influential literary tradition of satire, parody and aphorism devoted to 'defacing the currency' (that is, the dominant ideologies of the time). It proposes a new morality based on minimizing creaturely needs in pursuit of self-sufficiency (*autarkeia*), achieved in part by physical training (*askēsis*), and on maximizing both freedom of speech (*parrhēsia*) and freedom of action (*eleutheria*) in open defiance of the most entrenched social taboos; and an anti-politics which sees existing governments as a betrayal of human nature, and traditional culture as an obstacle to happiness. In their place, Cynics advocated an immediate relationship to nature and coined the oxymoron* kosmopolitēs *or 'citizen of the cosmos'. However the literary, ethical and political elements of Cynicism are interrelated, all are most easily defined by what they oppose - the inherited beliefs and practices of classical Greek civilization.*

The virtual loss of all early Cynic writings means that the history of Cynicism must be reconstructed from much later sources dating from the Roman Empire, the most important of which is Diogenes Laertius (third century AD*).*

1 The early Cynics

While ancient tradition consistently viewed Antisthenes (*c*.445-365 BC) as the first Cynic and Diogenes of Sinope as his pupil, modern scholarship has systematically questioned this view on chronological, numismatic and other grounds. What is at stake is nothing less than the relationship of Cynicism to Socrates, since Antisthenes was a prominent pupil of Socrates (present at his death) as well as of Gorgias the rhetorician.

Antisthenes wrote a great deal and, unlike later Cynics, his interests included theoretical as well as literary and ethical topics. It is probably more accurate to see him as an important forerunner (rather than as a founder) whose teachings provided Diogenes' practice with some basis in theory. Particularly relevant would be his beliefs that virtue (seeAretē) 'is a matter of deeds and does not needs lots of discourses and learning' and that it is sufficient for happiness 'since happiness requires nothing else except the strength of a Socrates'. If Xenophon follows Antisthenes in his representation of Socrates, then Antisthenes must have laid particular stress on Socrates' 'self-mastery' (*enkrateia*). In his *Symposium* Xenophon represents Antisthenes as actually praising poverty, which certainly resonates with Cynicism. The biographer Diogenes Laertius says that Antisthenes provided the model for Crates' 'self-mastery' and Diogenes' 'imperturbability' (*apatheia*), which he learned by imitating Socrates, thereby inaugurating the Cynic way of life.

Whatever his relationship to Antisthenes, Diogenes of Sinope (412/403-324/321 BC) was the paradigmatic Cynic of antiquity. While Diogenes probably produced written works that do not survive, including a *Republic*, for us his life and thought are inseparable, since the latter is conveyed almost entirely by a tradition of biographical anecdotes that was over 500 years old by the time of our primary source, Diogenes Laertius. Diogenes Laertius preserves over 150 sayings or anecdotes that purport to quote Diogenes verbatim, as well as some brief paraphrases of his philosophy (VI 70- 3), which may be even less reliable in so far as they reflect Stoic and other influences. Their historicity is always problematic, but their representation of Diogenes is the most valuable evidence we possess. Almost one in six of the anecdotes involves some form of word play or allusion to poetry. The form in which Diogenes is transmitted has two crucial features that a summary of his teachings might fail to convey. First, most of the anecdotes involve Diogenes responding wittily to some challenging question or circumstance: he is shown as a satiric provocateur as well as a heterodox moralist, and both sides of his nature

need to be kept in view; if what Diogenes represents is reduced to a simple, practical morality much that made him influential is lost. Second, the biographical form necessarily makes the philosopher the embodiment of his thought; this unity of theory and practice was to become an explicit principle of Cynicism and an important source of Diogenes' authority as a philosopher. It made him (like Socrates) emblematic of the philosophic life in antiquity.

If the anecdotes, and the metaphors and slogans they inspired, are the core of ancient Cynicism, Diogenes' philosophy begins with the fact of his exile from Sinope for (literally) defacing the local currency. When reproached for his exile, he replied: 'But that was how I became a philosopher, you miserable fool!' Asked what good he had got from philosophy, he replied: 'If nothing else, then to be prepared for every kind of luck.' Diogenes describes himself by quoting a fragment from an unidentified tragedy:

Without a city, without a house
without a fatherland
A beggar with a single day's bread.

This is the starting point of Cynicism: it is, among other things, an attempt to show that we are so constituted by nature that, given proper training (*askēsis*), happiness is possible under the most adverse conditions.

It is tempting to see Diogenes as transforming into an act of conscious defiance the exclusion he suffered involuntarily when forced into exile. This defiant stance became his 'philosophy' in a concerted attempt to demonstrate by his own example that happiness does not depend on society or on any contingent circumstance, the domain of Fortune, but wholly on the autonomous self - a self brought into existence, not by years of laborious text-based studies such as those advocated by other philosophers, but by Cynic discipline based on exemplary acts and corporeal training. This is why Cynicism came to be called a 'shortcut to virtue'.

The Cynic shortcut 'defaced' the value philosophers attached to theoretical disciplines as well as the conventional value society attached to such externals as money, status, family and political power. (Yet the most influential Hellenistic schools - Stoicism and Epicureanism - would follow the Cynics in arguing that the happiness of the sage *should be* independent of context.) Thus Diogenes' life becomes an extended counter-example meant to refute his critics, both popular and philosophical, as he turns the cause of his exile into a metaphor for his activity as a philosopher - 'defacing the currency' of conventional wisdom. 'Defacing' took the form of literary parody and satire, provocative acts of free speech (*parrhēsia*) and public exhibitions of the Cynic way of life. The laughter they were meant to provoke is an indispensable element of Diogenes' practice and served to reinforce his independence by distancing him from the rules that everyone else obeyed.

2 Diogenes' conception of the human being

If Diogenes differed from his contemporaries on the sufficient conditions for happiness, it is because they differed in their conception of the human being. Some of the most famous anecdotes dramatize Diogenes' rejection of the prevailing conceptions of the human, such as when he lit a lamp in broad daylight and walked around saying 'I'm looking for a human being', or when Plato defined a human being as a 'featherless biped' and Diogenes produced a plucked chicken, saying, 'Here is Plato's human being'.

Diogenes' positive conception of human nature is given, as always, by his own example, not by definitions. From it we can infer that for the Cynic human beings are animals who have much to learn about freedom and self-sufficiency from their fellow creatures. As well as offering ethical instruction, the use of animals as examples served to illustrate the intrinsic superiority of nature to culture. Theophrastus reports that Diogenes discovered how to adapt to circumstances by carefully observing a mouse. Such adaptability enabled him to test the limits of his species by living like a dog in an abandoned wine-jar (*pithos*). A string of anecdotes develop different aspects of the canine metaphor: among Diogenes' canine characteristics was a shameless indifference to social norms, which enabled him to discard traditional morality based on shame in favour of living naturally and freely - that is, fulfilling his essential creaturely needs for food, sex and shelter without regard for the restraints and prohibitions of culture. Yet unlike sophists such as Callicles, the Cynics never used nature to sanction dominating others (although theft was another matter). Clearly, the Cynic rejection of shame cannot be reduced to a matter of manners as opposed to morals: Diogenes' pursuit of life according to nature led him to question the rational basis of such fundamental dietary and sexual taboos as those against cannibalism and incest, citing examples from

nature and non-Hellenic cultures.

While advocating a rigorous physical training intended to inure one to inevitable hardship, Diogenes showed no aversion to pleasures compatible with his way of life. Indeed, he used ‘any place for any purpose’, exemplifying the Cynic conception of freedom, which applied to sexual activity - from free love to public masturbation - as well as to eating, sleeping and talking. But the ultimate aim of imitating the freedom and self-sufficiency of animals is neither instinctual satisfaction nor mere ‘imperturbability’ (*apatheia*), but the Olympian independence of the gods, who, ‘needing nothing’, live easily free of mortal cares. Hence, Heracles, the one mortal to reach Olympus by triumphing over his famous labours, was adopted and re-interpreted by the Cynics as their mythical prototype. Diogenes explicitly claimed that their life had ‘the same character’ because both ‘deemed nothing more important than freedom’.

Of course Diogenes’ Cynicism is full of paradoxes. While teaching life according to nature and denouncing existing social arrangements, Diogenes went on living in cities, which he made no attempt to reform. While advocating freedom and self-sufficiency as paramount values, he both practised and advocated begging for a living. We must resist the temptation to turn a remarkable experiment, which challenged the most fundamental ideas of Greek civilization, into a mere system.

While Diogenes probably had no pupils as such, his example (whether conveyed orally or by written works) effectively established a philosophical model that invited imitation and interpretation. In the absence of a systematic body of doctrine, the nature of Cynicism was always up for debate; all the Cynics of antiquity as well as those who represent them (for example, Lucian, Dio Chrysostom) were of necessity actively engaged in interpreting the tradition, whether by word or deed.

3 Diogenes’ successors

The most influential Cynic in antiquity after Diogenes was Crates of Thebes (*c*.368-*c*.283 BC), a wealthy landowner and therefore at the opposite end of the social spectrum from a poor exile like Diogenes. He was a hunchback and several anecdotes refer to his comic appearance. He married Hipparchia of Maronea, who, along with her brother Metrocles, became a practising Cynic and, as such, the most famous female philosopher of antiquity. Their Cynic marriage (*kynogamia*), based only on mutual consent, was consistent with Diogenes’ views but radically at odds with Greek custom. The tradition holds that Hipparchia adopted the simple Cynic garb of Diogenes - a rough cloak, knapsack and staff - and lived on equal terms with her husband, attending events usually reserved for men and successfully defending her decision to pursue philosophy instead of weaving. Crates and Hipparchia were also notorious for living and sleeping together in public places, Cynically indifferent to shame and public opinion. It was Crates who described the fruits of philosophy as ‘a quart of beans and to care for naught’.

However Crates came to know Diogenes, his life was a remarkable application of the Cynic’s principles. He clearly regarded himself as a follower, calling himself a ‘fellow citizen of Diogenes’. There are several (probably fictitious) accounts of how Crates became a Cynic, which revolve around the fact that he evidently sold all his possessions and gave the proceeds to his fellow citizens, thereby embracing poverty, as had Diogenes. In contrast to Diogenes with his combative style and acerbic tongue, Crates was remembered as a benevolent figure and, thanks to his role as arbiter of family quarrels, actually revered as a household deity in Athens. But his fragments are clearly informed by a satiric (or seriocomic) perspective, the hallmark of Cynic discourse: ‘He used to say that we should study philosophy until we see in generals nothing but donkey-drivers.’

Crates was one of the most influential literary figures of the fourth century and his writings did much to disseminate Cynic ideology and establish parody as a distinctly Cynic mode of ‘defacing’ tradition. His *oeuvre* is notable both for its originality and its variety. He composed ‘tragedies’, elegies and epistles, and parodies such as his poem in hexameters entitled *Pēra (Knapsack)*, a hymn to frugality, a *Praise of the Lentil*, and an *Ephēmerides (Diary)*.

After Crates came Menippus (first half of the third century BC). The unreliable biographical tradition depicts him as a Phoenician slave who acquired his freedom by begging or usury and hanged himself when his business failed. Be that as it may, Menippus is among the most influential of Hellenistic authors. He is the only Cynic expressly called *spoudogeloios* (‘seriocomic’) in antiquity, and is credited with the invention of Menippean satire, a form of

narrative satire that parodies both myth and philosophy. The imitations and adaptations of his work by Varro (116-26 BC) and Lucian gave Menippean forms a long and influential afterlife in antiquity and the Renaissance, making Cynicism one of the primary sources of satiric literature in Europe.

Bion of Borysthenes (*c*.335-*c*.245 BC) also played an important role in early Cynicism, especially in the domain of literature. Tradition holds that he was sold into slavery as a boy but was bought by a rhetorician and received a rhetorical education. Later, he evidently received an eclectic education in philosophy at Athens: he studied with the Academics (under Xenocrates and Crates), with the Cynics, Cyrenaics and, finally, the Peripatetics. Bion probably originated the literary form of the diatribe - an argumentative monologue with imagined interlocutors, which was an important model for satirists and essayists of the Empire. Because Bion's Cynicism seems less radical and more opportunistic than that of Diogenes, it has sometimes been characterized as a 'hedonizing Cynicism'. References in Horace and other writers suggest an eclectic thinker with remarkable literary talents, as do his witty fragments.

Teles (*fl. c*.235) was a teacher and moralist who quoted extensively from such philosophers as Diogenes, Crates, Metrocles, Stilpo and Bion, his favourite authority and model. The surviving seven excerpts of his *Diatribes* are the earliest examples we possess of this influential Cynic tradition.

The works of Cercidas (*c*.290-220 BC), the last important early Cynic, take a surprising political turn. Cercidas was unusual for a Cynic in being a soldier, politician and lawmaker as well as a poet. He is best-known for his *Meliambi* (written in the Doric dialect), in which he uses a lyric form to mount a serious Cynic critique of contemporary politics.

4 Cynics in the Roman Empire

Whatever the causes of its apparent decline after Cercidas, when Cynicism re-emerges in the Roman Empire, it has changed, as has the world. In a series of confrontations under the emperors Nero, Vespasian and Domitian, Roman aristocrats with republican sympathies were put to death and the philosophers associated with them - both Stoics and Cynics - were banished from Rome. The best known Cynic of the period, Demetrius, a friend and hero of Seneca, is the most conspicuous example of the Cynic involvement in the 'philosophical opposition' to the emperor.

The emergence of Cynicism as a potent political ideology - opposed to hereditary monarchy - in the first century AD is highly significant but potentially misleading: most Cynics did not live in Rome nor in the West but in the Greek-speaking cities of the East from Athens to Alexandria. Most were not politically active but busily engaged in living the Cynic way of life - begging their daily bread and bearing witness to the example of Diogenes. Socially their status had been extremely mixed from the beginning, but as a rule they were not the associates of men of wealth and power such as Seneca. The sight of vagrant Cynics living in groups, travelling from city to city dressed in the Cynic garb, was not uncommon in the Empire. In the centuries since its inception Cynicism (alone among the philosophical sects) had become a popular movement attracting adherents from those strata of society outside the traditional audience for philosophy. It is impossible to quantify the movement, but more than eighty known Cynics have now been identified.

The most prominent Cynics of the Empire - Demetrius, Demonax of Cyprus (second century AD) and Peregrinus Proteus of Parium (*c*. AD 100-65) - were, unlike the early Cynics, teachers, not writers, and what we know of them is filtered through writers with their own philosophic interests, such as the Stoic Seneca and the satirist and sophist Lucian. Indeed, one of the central paradoxes of Cynicism's reception in the Empire is that the influence of Cynic ideology reached its apogee (in the second century AD) when very little in the way of original Cynic literature was being produced by practising Cynics. Oenomaus of Gadara (second century AD) is the only Cynic of the Empire known to us by his written work, *Charlatans Unmasked*, a lively, if not particularly original, attack on the veracity of oracles that survives because it is quoted by Eusebius, but does not seem to have made a great impression on Oenomaus' contemporaries. His other works, including 'tragedies' that scandalized the pious emperor Julian, are lost.

The only literature produced by Cynics in the Empire that we can set beside that of Oenomaus are the *Cynic Epistles*, a collection of fictitious letters attributed to the early Cynics and other sages. The authors of the letters are unknown and their dates of composition may vary considerably (from the third century BC to the second

century AD). The epistles offer an informative survey of the topics, slogans and anecdotes that must have fuelled many a 'diatribe', the term conventionally used to describe the oral performances of the Cynic street preachers so often remarked on by our sources. These oral performances were probably the primary means by which Cynic teachings were disseminated among the general populace. The *Cynic Epistles* confirm the impression that Cynic literary production in the Empire was no longer marked by the innovative parodies and polemics of the classical period and now served primarily to propagate Cynicism as a popular ideology and collective moral praxis.

We must remember, however, that our most important sources (other than Diogenes Laertius and the *Cynic Epistles*), the sophists Lucian (*c*. AD 120-80) and Dio (*c*. AD 40-111), the Stoic Epictetus (*c*. AD 55-120) and the emperor Julian (*c*. AD 332-61) probably had access to classic works by the early Cynics as well as a secondary literature that grew up around them. Both Dio and Lucian draw on these lost traditions to create a contemporary Cynic literature in which Diogenes and other legendary Cynics (Antisthenes, Crates, Menippus) appear as characters. Their works give us the liveliest images we have of what the lost Cynic classics might have been like and (along with Diogenes Laertius) are among the primary means whereby Cynicism became part of the philosophical and literary culture of Europe.

Lucian's use of Cynic traditions is too complex to characterize briefly, but Cynic ideology and the example of the Cynic classics were indispensable to him: they gave him a licence to satirize all things Greek, which now of course included Cynics and Cynicism itself. It is Cynicism as a radical form of cultural criticism - of 'defacing' the idols of the tribe through parody, satire and free speech - that led Lucian to adopt Cynic forms (for example, Menippean satire) and voices in so many works. But his *Life of Demonax* also shows a serious interest in using Cynic (and Socratic) traditions eclectically to construct a contemporary ethical model.

Similarly, Dio - who claims to have lived as a Cynic when in exile - uses the authority of Diogenes' persona in an important series of speeches to advocate Cynic values of particular importance to him as a courtier, particularly autonomy and freedom of speech. While lacking some of the Cynic seriocomic qualities that Diogenes has in Diogenes Laertius or Lucian, Dio's Diogenes is, on the whole, surprisingly true to his persona in the anecdotal tradition. Epictetus, by contrast, offers a distinctly idealized, quasi-religious account of Cynicism as a philosophical vocation and practical philosophy. His emphasis on praxis invites comparison with that of the *Cynic Epistles*. Julian echoes some of Epictetus' religious tendencies while arguing that Cynicism is a universal philosophy founded not by Diogenes nor Antisthenes, but by Apollo and based on the dictum 'Know thyself'.

Yet despite the obvious affinities all these authorities have for Cynic traditions, all denounce contemporary Cynics in the harshest terms as ignorant impostors. It is clear that the Cynic movement had split along the lines of class, wealth and education - the very distinctions Cynicism sought to annul. What we hear in the denunciations of our sources are the traces of a heated argument over the Cynic legacy. What is the ultimate value of Cynicism? As a practical ascetic morality for the have-nots, as a universal ethical model of freedom and autonomy, or as a cultural practice devoted to 'defacing' the false values of the dominant culture? Who has the right to speak out in the name of Diogenes? It is an argument that would resound from the humanists of the Renaissance to the *philosophes* of the eighteenth century, when Diderot wrote his Encyclopedia article on the Cynics and his Cynic masterpiece, *Rameau's Nephew*, exploring the relation between Cynicism, cynicism and the nature of enlightenment.

Cyrenaics

The Cyrenaic school was a Greek philosophical school which flourished in the fourth and early third centuries BC*. It took its name from the native city of its founder, Aristippus of Cyrene, a member of Socrates' entourage. His most important successors were his grandson, Aristippus the Younger, and Theodorus, Anniceris and Hegesias, the heads of three separate Cyrenaic sects.*

The basis of Cyrenaic philosophy is physiological and psychological. It focuses on the individual feelings of pleasure and pain which are classed as pathē*, experiences produced in a subject by its contact with an object. They are described, respectively, in terms of smooth and rough movements, of the flesh or of the soul. A third category of* pathē*, described as intermediate between pleasure and pain, is also defined as movements and related to one's perception of individual properties or qualities. All* pathē *are short-lived and have no value beyond the actual time of their occurrence.*

These physiological characteristics are encountered both in the ethics and in the epistemology of the school. Although the Cyrenaics differed in their ethical doctrines, all of them attributed a central role in their systems to the individual bodily pleasure experienced in the present moment, and some of them considered it the moral end: it is pursued for its own sake, whereas happiness, conceived as the particular collection of pleasures that one experiences during a lifetime, is sought for the sake of its component pleasures. The goodness of individual pathē *of pleasure is supported by an elaborate epistemological doctrine whose central claims are that we are infallibly and incorrigibly aware of the occurrence and content of our own* pathē*, but that we cannot apprehend the properties of external objects. A striking feature of this doctrine is the neologisms designating the perception of qualities, such as 'I am whitened' and 'I am affected whitely'. This, and other features of Cyrenaic subjectivism, anticipate some modern philosophical analyses of subjective experience.*

1 History of the school

The Cyrenaic school was founded by a close associate of Socrates, Aristippus of Cyrene (see Aristippus the Elder), after Socrates' death (399 BC) and probably after Aristippus' numerous travels. For three successive generations its scholarchs (school heads) were members of the same family: Aristippus was succeeded by his daughter Arete (born *c*.400 BC) and then by his grandson, Aristippus the Younger (born *c*.380 BC). Our sources mention also Antipater of Cyrene, Aethiops and, later, Epitimides and Paraebates, but almost nothing is known about their careers as scholarch. Aristoteles of Cyrene apparently belonged to the same generation as Aristippus the Younger. At the beginning of the Hellenistic period (323-31 BC), the Cyrenaics Theodorus, Anniceris and Hegesias each founded a separate sect. Each sect was identified by the name of its leader ('Theodorians', 'Annicerians', 'Hegesians') but also preserved its Cyrenaic affiliation. It seems likely that, during the same period, there was yet another sect bearing the original name of the school and claiming to represent Cyrenaic orthodoxy. The Cyrenaic sects disappeared in the second half of the third century BC, some time between Arcesilaus' death and Chrysippus' appointment as head of the Stoa.

Of the Cyrenaics' writings, only some titles survive. Aristippus the Elder is credited with several Socratic dialogues on various ethical themes and with a three-volume history of Libya. Theodorus was the author of an influential treatise entitled *On the Gods* which attempted to refute traditional Greek theological beliefs. Hegesias composed a book entitled *The Self-Starver* enumerating the calamities of life, which may have aimed to procure an empirical basis for his moral pessimism.

Some sources maintain that the Cyrenaics devoted themselves exclusively to ethics, disallowing physics and logic as branches of philosophy. However, there is good evidence that they accepted logic as a tool of philosophical argumentation, and that they developed epistemology as a separate subject of inquiry, not as part of ethics or logic.

2 Epistemology

The origins of Cyrenaic philosophy were ethical, the epistemology probably being developed in the third generation of the school by Aristippus the Younger. However, the founder of the school laid the physiological and psychological foundations of the Cyrenaic theory of knowledge, mainly by his analysis of the notions of pleasure and pain, which was endorsed by his successors.

Pleasure and pain are *pathē*. The term belongs to a group of words related to the Greek verb *paschein* (to undergo) and refers to effects upon a subject, usually caused by an external object. The word can be used both regarding an inanimate substance and regarding a perceiving subject: a stone exposed to the sun may turn hot, or a person in a warm room may feel hot. Although the Cyrenaics focused on the *pathē* in connection with perceivers, their analysis preserves physicalist overtones. These are particularly obvious in the definitions of pleasure and pain as smooth and rough movements, of the flesh or of the soul, related to pleasurable and painful feelings. Some sources define that relation as an identity, but there is good evidence that the Cyrenaics drew a distinction between the physical motion associated with pleasure or pain and the subjective experience of *feeling* pleasure or pain. Since the motions associated with the *pathē* disappear with time, the *pathē* are short-lived. The memory of past pleasures and the anticipation of future ones is not really a pleasure, and presumably the same holds for pain as well. There are conditions in which a perceiver experiences neither pleasure nor pain: according to the Annicerians, the states of the absence of pleasure (*aēdonia*) and of the absence of pain (*aponia*) are not *pathē*, for they are not related to motions but are comparable to the state of someone asleep. On the other hand, Aristippus the Younger introduced a third category of *pathē*, which are associated with motions and defined as intermediate between pleasure and pain. They represent the manner in which one is affected by one's perception of the empirical qualities of an object and are reported by verbal or adverbial neologisms, such as 'being whitened' or 'being affected whitely', and 'being sweetened' or 'being disposed sweetly'. Pleasure and pain, as well as the intermediates, are sensed by 'inmost' or 'internal' touch. Although the sources say nothing further about this, it seems likely that the function of internal touch is to register the qualitative alterations of the flesh, and thus to provide a necessary and sufficient condition for one's awareness of one's own *pathē*.

These characteristics of the *pathē* constitute the basis for the Cyrenaic theory of knowledge, whose full formulation probably coincided with the introduction of the intermediates into the doctrine. It is centred on the subjectivist claim that the only knowledge accessible to one is the awareness of one's own *pathē*, and on the dogmatic assertion that the nature of external objects cannot be known.

Although the Cyrenaics draw no sharp distinctions between the physical and mental aspects of the *pathē*, in the context of their epistemology they clearly concentrate on the latter: one's apprehension of the *pathē* concerns primarily the subjective experience that one has. For, first, the Cyrenaics distinguish between the smooth movement associated with pleasure and the sensation or consciousness (*aisthēsis*) of it. Second, their use of adverbial expressions, such as 'being disposed whitely', is applicable to perceivers only, and inapplicable to inanimate objects undergoing purely physical change. And third, the *pathē* are, according to the Cyrenaics, self-presenting states which cannot yield false information about themselves to the person who experiences them. This only makes sense if the *pathē* are taken to be the immediate contents of experience rather than objective physical states.

This is confirmed by their insistence on the privacy of experience: each *pathos* is private (*idion*) to the individual perceiver experiencing it. Autobiographical reports regarding one's own *pathē* are infallible (*adiapseusta*), incorrigible (*anexelenkta*), always firm (*bebaia*) and true (*alēthē*). Thus, one has privileged access to one's own *pathē*, which may be related to the way in which they are detected by 'internal touch'. By contrast, the Cyrenaics stressed the structural and definitional inaccessibility of other people's *pathē* by arguing that people cannot have a common, that is, publicly shared, *pathos* which might be used as a common criterion of truth. The private character of the *pathē* is also said to make them incommunicable to others.

The incorrigible awareness of the *pathē* is contrasted with one's ignorance of external objects. The scope of Cyrenaic scepticism is limited in that it does not question in a radical and systematic way the actual existence of objects and, consequently, does not raise the so-called problem of the external world. It concerns mainly our knowledge of empirical properties or qualities and is supported by the argument that our beliefs about them are in reality beliefs about the content of our *pathē*, and that no one can transcend the barrier between objective properties and our perception of them. Since the causal history of a *pathos* cannot be traced back to the objective property which it is ordinarily supposed to represent, our beliefs regarding the properties of objects can be neither confirmed nor refuted by further evidence of any kind.

The Cyrenaics appear to have focused on specific problems, mostly related to the perception of secondary qualities, and did not try to provide a general epistemological theory. Important criticisms that can be brought

against their position include the following: (1) the claim that only the *pathē* are apprehensible is too narrow to justify our ordinary assumptions about what we know; (2) the theory is either inexpressible or self-refuting; (3) it entails a radical subjectivization of all experience, which raises doubts, unwelcome to the Cyrenaics themselves, about the very existence of the external world and of other people.

3 Early Cyrenaic ethics

It has been commonly held that the Cyrenaics were the only philosophers in antiquity to abandon the traditional position of Greek ethics; that the moral end is happiness (see Eudaimonia), and to identify it instead with individual bodily pleasure experienced in the present moment. However, this position overlooks the value that the Cyrenaics attributed to happiness as well as to individual pleasures, and fails to account for the significant differences between the ethical doctrines of various members of the school.

There are two groups of testimony about the ethical views of Aristippus the Elder. According to one, he was a hedonist (see Hedonism) who defined the moral end as a smooth movement resulting in a short-lived pleasure of the body. He distinguished it from happiness, the particular collection of individual pleasures experienced over a lifetime. But according to the second body of testimony, Aristippus did not define pleasure as the only thing which is intrinsically good, nor did he maintain that it is only pleasure and not happiness that is pursued for its own sake. Although he appears to have conceived of happiness in compositional terms and to have considered pleasure its major constituent, he believed that the enjoyment of pleasure should be conditional upon the capacity to master oneself. This is acquired by means of philosophical education, which also secures spiritual freedom, self-awareness and, more generally, the well-being of one's soul. Provided that these goods are obtained, one may indulge in many and intense pleasures without the fear of enslaving one's soul.

Regardless of the origins of the two traditions, there are good reasons for accepting the latter. First, there is evidence that Aristippus never lectured in defence of a particular moral end and that he detested adopting a didactic tone. This tells against his having argued on behalf of a well-defined hedonistic position and, perhaps, in favour of his having shared the common assumption that the supreme good is happiness, however defined. Second, one source, the Peripatetic Aristocles, flatly denies that Aristippus was a hedonist, and adds that he was only thought to be so on the grounds of his intemperate habits. Third, the importance which he attributed to long-term activities such as philosophy, and his statements that he aims at the easiest and pleasantest life and that he wishes to live a life of freedom leading to happiness (Xenophon, *Memoirs of Socrates* II 1) indicate that he perceived his life as a continuous whole, not as a series of disconnected pleasurable episodes. On that account, too, he seems closer to eudaimonism than to hedonism. Finally, the relationship of Aristippus to Socrates and the claim of his school to a Socratic pedigree make it difficult to believe that he would have held a view which entailed that any means to the pleasure of the present is acceptable and which, therefore, would have verged on the immoral.

The value that Aristippus attributed to a life of freedom and happiness recurs in his political stance. According to Xenophon, he declined to assume the civic roles of ruling or of being ruled which were necessarily attached to the political condition of citizenship and, instead, chose for himself the apolitical stance of 'living as a foreigner in every land'. Thus, he defined freedom not only as internal freedom, but also as freedom from duties and obligations with regard to any particular city. His motivation for assuming this position was eudaimonistic: only the life of a foreigner affords the type of freedom that leads to happiness.

Aristippus the Younger was probably the first Cyrenaic philosopher to single out momentary bodily pleasure as the moral end. He appears to have conceived of the moral end as complete and perfect, for he maintained that bodily pleasures do not differ in intensity or degree: none is more pleasurable than another, presumably because no particular instance of the moral end can be more perfect, and therefore more worthy of choice, than another. He distinguished between happiness and the moral end by defining happiness as a particular collection of individual pleasures experienced over one's lifetime, and by claiming that happiness is not desirable for its own sake but for the sake of the pleasures composing it. However, his hedonistic ethics is not altogether devoid of eudaimonistic considerations. For he believed that the overall moral goal is to live a pleasurable life, thus emphasizing the importance of accumulating the particular pleasures which jointly compose a happy life. Such considerations arguably precluded him from holding the view that all means are permissible for obtaining pleasures. For some means to a particular pleasure may obstruct the achievement of subsequent pleasures or may have painful after-effects, and thus may affect one's enjoyment of a happy life.

4 Later Cyrenaic ethics

The ethics of Anniceris and of Hegesias also rest on a delicate balance between hedonism and eudaimonistic elements. Anniceris and his disciples further clarified the notion of the moral end by emphasizing that pleasure and pain are necessarily related to motion and by arguing that, since the condition of mere absence of pain is not characterized by motion, it cannot be part of the moral end. Their thesis should be contrasted with the position of the rival school of Epicurus, according to which the supreme moral good is static pleasure, characterized by the complete absence of pain (see Epicureanism §10). They broadened Aristippus the Younger's definition of the moral good by attributing intrinsic moral value to mental as well as bodily pleasure, and allowed for circumstances in which sages will act altruistically and deprive themselves of pleasures, but will none the less be happy. Anniceris' concern with the repetition of individual pleasures and the enjoyment of new pleasures over an extended period of time is also indicated by his recommendation of forming good habits in order to correct a naturally bad disposition, and friendships on account of the repeated good feelings that they cause us.

Hegesias was a hedonist in principle, since he too defined the momentary present pleasure as the moral end. However, he added that one scarcely enjoys such pleasures, whereas one suffers numerous pains during one's lifetime. On these grounds, he concluded that the collection of individual pleasures constituting happiness cannot be achieved. The unattainability of happiness led him to maintain that life is a matter of indifference, and that life and death are each desirable in turn. His pessimism is moderated by the intellectualist position that no one errs voluntarily, and by the philanthropic concern that one should not despise other people but teach them.

Theodorus radically modified the hedonism of the other Cyrenaic sects. He introduced the concepts of joy and grief, defining joy as the supreme moral good, and claimed that pleasure and pain are intermediate between good and evil. Although he did not speak openly of happiness, his position has clearly eudaimonistic dimensions. For he viewed particular pleasures instrumentally, as means to joy, and he believed that joy results from the exercise of wisdom and justice. For these reasons, it seems likely that he conceived of joy as a long-term pleasurable state akin to happiness. His doctrine is comparable to the views of Aristippus the Elder: he considered wisdom and justice to be goods and emphasized their importance for achieving the moral end; he maintained that the sage need not be temperate in the enjoyment of pleasure, but unlike Aristippus the Elder did not make it conditional upon the capacity for mastering oneself; and he stressed the self-sufficiency of the sage, advocated cosmopolitanism and considered irrational the performance of military duty for any particular city. On the other hand, Theodorus introduced into Cyrenaic ethics an atheism and an amoralism which are not encountered in the doctrines of his predecessors.

The ethical doctrines of the Cyrenaics, regarding both the central role of pleasure and the importance of happiness, appear to find support in their epistemology. Since any momentary pleasure is a *pathos*, the manner in which it affects one is infallibly apprehended. It could be argued that we infallibly apprehend not only the pleasurable nature of the experience but also its self-evident goodness. Regarding the desirability of a happy life, the Cyrenaics could maintain either that it is itself a *pathos*, so that its content is indubitable, or that the goodness of a pleasurable life is self-evident in so far as the goodness of its component pleasures is self-evident. This connection between their ethics and their epistemology is admittedly no more than a conjecture and invites the objection that moral properties such as goodness are not part of the self-evident content of a *pathos*. Further, even if the goodness of every individual *pathos* of pleasure were self-evident, it would not straightforwardly follow that a collection of such *pathē* must preserve the goodness of the pleasures constituting it.

5 The Socratic connection

Historically, the Cyrenaic school owes its Socratic pedigree to the inclusion of its founder, Aristippus of Cyrene, in Socrates' entourage (see Socratic Schools). Philosophically, there are several elements both in its epistemology and in its ethical doctrines that would justify the claim that it remained close to the spirit of Socrates' teachings.

Concerning their theory of knowledge, the Cyrenaics might argue that, like Socrates, they obeyed the Delphic maxim 'Know yourself!' and came to the conclusion that one cannot know anything but oneself. Thus, both the description of the physical states related to the *pathē* and the epistemic analysis of our apprehension of them could be inscribed in the context of an effort to pursue further the Socratic example of self-knowledge. Further, they could appeal to Socrates' disavowal of knowledge in support of their position that one is necessarily bound to be

ignorant about external objects, thus endorsing, or perhaps even inaugurating, the tradition which made Socrates the founder of scepticism.

As regards their ethical doctrines, the Cyrenaics could make the general remark that even the Platonic Socrates, whether or not a hedonist, considered the enjoyment of mental pleasures compatible with the existence of a virtuous state of soul, and did not disallow all bodily pleasures, but only those which endanger self-mastery and moderation. Finally, most Cyrenaic philosophers appear to have endorsed some version of Socratic intellectualism - perhaps the most important motivation for calling them a Socratic school.

Czech Republic, philosophy in

The foundation of the University of Prague in 1348 contributed significantly to establishing Bohemia as a centre of philosophical thought. The main philosophers and theologians from the University favoured the Platonic tradition, and from this position they criticised corruption in the Church. The most important representative of this trend was Jan Hus who followed the teaching of John Wyclif in the spirit of rationalism and humanism. His ideas became an ideological base for the anti-feudal Hussite Revolution in the fifteenth century and the later Czech Reformation. Theoreticians on the extreme wing of the Revolution held a natural worldview, opposing the notion of transcendence. Social thinking in this era found expression in Petr Chelčický, who preached a strict pacifism and a classless society. The Revolution broke the power of the Church's ideological monopoly, and had a positive impact on the development of Czech society for the following two centuries. The atmosphere of relative tolerance allowed Renaissance thinking and Czech Reformation rationalism and humanism to enrich each other. This tradition culminated in the work of Jan Amos Comenius, who aimed to improve social relations through rational enlightenment and education, promoting harmony and justice for the development of all humankind.

After 1620, Czech spiritual life was paralysed for many centuries by a forced anti-Reformation and the emigration of many of the country's leading intellectuals. A revival started only at the end of the eighteenth century. František Palacký, inspired by the neohumanism of his era and by the Czech Reformation, formed a new philosophy of Czech history. B. Bolzano achieved impressive results in philosophy of science and logic, while A. Smetana created an independent variant of the philosophy of identity. In the second half of the nineteenth century Herbartism became very influential, contributing to social psychology and aesthetics.

The most important representative of modern Czech thinking is T.G. Masaryk, creator of a philosophical concept of democracy understood in the context of a humanistic world view. Masaryk's philosophy has been followed by many philosophers and theologians in the twentieth century. In the period between the wars, important concepts based on structuralism were created by J.L. Fischer (philosophy, sociology),J. Mukařovský (aesthetics), V. Příhoda (psychology, pedagogy), and many linguists. J. Patočka contributed to the development of phenomenology with his concept of the natural world. In opposition to 'school' philosophy L.Klíma preached extreme subjectivism and individualism. Non-dogmatic Marxists wrote internationally regarded works. Well known in analytical philosophy and modern logic are the achievements of L. Tondl, O. Weinberger, K. Teige, R.Kalivoda and K. Kosík and P. Tichý.

1 Early period

Philosophy in the Czech Republic is connected to national history in a manner unlike any other European 'philosophical' country. It has sometimes had to disregard academic problems and interests to join the social battles of the era, and so it has played a major ideological role. Often it has had to reach beyond itself to develop ideas in other spheres of spiritual life, from the literary and historical to the natural sciences. The beginnings of philosophy in Bohemia go back as far as the thirteenth century to the Prague Cathedral School, which had contact with other European centres of philosophy. The founding of Prague University in 1348 was a positive stage in the development of philosophical scholarship, and important philosophical trends were evident at the University from the beginning. With time, however, realism in opposition to nominalism prevailed, based on the Platonic traditions of European thinking (see Nominalism). The chief representative was Vojtěch Raňkuv of Ježov (Adalbert Rankonis) (d. 1388), a Rector of the Sorbonne who introduced the writings of John Wyclif to Prague University. Others include Jan Milíč of Kroměříž (d. 1374), a severe critic of both secular and Church power who influenced later Hussite thinkers with his chiliastic image of the coming doomsday and the 'era of justice'; Matěj (Mathias) of Janova (d. *circa* 1394), who denounced the institution of the church and demanded the creation of a *communio sanctorum* (community of saints) modelled on the first Christians; and Tomáš of Štítný (d. *circa* 1405), the first scholar to write his critical essays in Czech and the founder of Czech philosophical terminology.

This movement culminated in the early fifteenth century with Jan Hus, whose philosophy built on the achievements of Wyclif to reach humanistic and rationally critical conclusions. Hus believed that every Christian has the right to use their reason to judge the laws of the secular world as well as Church powers, as well as the right to refuse to obey if they find any discrepancies between these and God's law (understood as a Platonic Idea).

The truth wins only when a man is willing to sacrifice his own life for it. Hus attempted to defend his ideas before the Church Council in Konstanz, but failed and was burnt at the stake. After his death, his ideas became an ideological starting point for the Hussite Revolution (1419-34) and the Reformation that followed. His influence was widespread: Jakoubek of Stříbro' (Jacobellus of Mies) (d. 1429), an ideologist of the mild wing of the Hussite Revolution, introduced Holy Communion from the chalice as a symbol of Christian equality for all believers; Mikuláš Biskupec (d. *circa* 1460) represented the radical wing and preached the 'liberal law of the Lord' which was based on the spiritual and social emancipation of human beings; Martin Húska (d. 1421), an extreme left-wing Hussite ideologist, refused to accept any notion of transcendence and denied theist dogmas - for him, God lives in human beings and the Eucharist is a real material feast, all people are equal and sexual life should be free; Petr Chelčický (d. 1460), a social reformer, believed the feudal division of society to be unjust and claimed equal rights for everyone, calling for universal love and condemning all violence (his ideas later influenced L.N. Tolstoi).

The Hussite Revolution inspired the Czech Reformation, the first victorious reformation in Europe, and in 1457 a new Church was founded in Bohemia. Known as *Jednota bratrská* (Unity of Brethren), this new Church, was based on the teachings of Chelčický. Later it became an important centre of spiritual and cultural life in Czech society. (Many of its members emigrated in the seventeenth century before the violent anti-reformation broke out, and one of its branches still exists in the USA as the Moravian Brethren.) The 'Unity' proclaimed the idea of religious tolerance and, combined with other Reformation ideas, contributed to the forming of the 'Czech confession' (1575) which demanded freedom of belief for all - including serfs, thereby going against the feudal principle that they follow the beliefs of their ruler ('*cuius regio, eius religio*'). Among the representatives of the Unity was Jan Blahoslav (d. 1571), an outstanding bishop who wrote many theological and pedagogical essays, as well as the first Czech book on aesthetics and musical theory.

In Bohemia as elsewhere, the Reformation was followed by a surge in Renaissance humanism, both existing simultaneously and having mutual influence. In fact, representatives of both sides aimed to bring the two movements together. Viktorin Kornel of Všehrdy (d. *circa* 1520), a founder of the first Czech law school, worked on the philosophy of natural law, which reflected the self-awareness of the new class of citizens. He was also the creator of a philosophy of Czech history that overemphasized the importance of the Hussite period. Řehoř Hrubý of Jelení (Gelenius) (d.1514), a translator of Cicero, Petrarch and Erasmus of Rotterdam, was influenced by Stoicism and united his patriotism with the idea of Universal Goodness into a universally understood world view. Jan Jessenius (d.1621), a rector of Prague University who was executed for his part in the anti-Habsburg uprising, was a physician and a follower of Renaissance natural philosophy (inspired by Franciscus Patritius). He also supported Heliocentrists, as did the outstanding mathematician and astronomer Tadeáš Hájek (d.1600), whose work was used by Tycho de Brahe, Kepler and Galileo.

Prague at this time was also an important centre of Jewish culture. Its most important representative was Jehuda ben Becalel Liva (d.1609), the legendary Rabbi Löw who, in his chief philosophical and theological document *Be'er ha-gola* (1600) expresses his understanding of a free man opening himself to the outside world through his activity. Rabbi Löw also wanted the Jewish community to engage other nations in dialogue on equal terms.

Czech Reformation thinking, which was enriched by many elements from the Renaissance, culminates in the synthetic work of Jan Amos Comenius, the last bishop of the Unity. In his major work, *De rerum humanarum emendatione consultatio catholica*, he created a philosophical system dominated by the idea of amelioration and the harmonious arrangement of human relations, based on rational enlightenment and general education. He believed in human nature as an active force capable of constant improvement. Didacticism and pedagogy were to serve as an instrument to reach this aim. At he deepest layer of this conception there is an ontology based on a modified Neoplatonist scheme, whose highest degree is the harmonious development of all beings into a new human reality.

The movement in Czech philosophical thinking which culminated in the work of Comenius was interrupted after the Battle of White Mountain in 1620. The Czech State ceased to exist and a forced re-Catholicization of the country followed. The elite of Protestant intellectuals, including Comenius, had to leave the country and their place was taken by Catholic priests, mostly of foreign origin, who brought with them other intellectual traditions. Some of them contributed to the history of seventeenth-century philosophical thinking, including Roderigo Arriaga, a follower of the neoscholastics, who tried to find a compromise between the teaching of Thomas Aquinas

and William of Ockham in a spirit of mild realism; Jan Caramuel of Lobkowicz, considered a father of modern logic of relations; and Valerianus Magni, a Franciscan who developed the Scotistic tradition, opposed neoscholasticism and was close to Descartes' rationalism (see Descartes, R.; Duns Scotus, J.; Rationalism). Jan Marcus Marci of Kronland was a different type of thinker, a natural scientist rooted in Platonism and Neoplatonism who preached the analogical construction of microcosm and macrocosm - through studying the activity of nerves he arrived at ideas anticipating later associative psychology (see Neoplatonism; Platonism, Renaissance). Hieronymus Hirnheim belonged to the anti-Jesuit opposition. He stressed the ethical ideas of original Christianity, the primacy of life-praxis over speculative scholasticism and the importance of subjective belief oriented to a philosophy close to Jansenism.

2 From the National Revival to 1918

After the long period of oppression, Czech intellectual life was slowly revived in the last third of the eighteenth century. It was inspired first by the Enlightenment, later by neohumanism and romanticism, and at the same time by the older national tradition of the Reformation. It paid great attention to the development of the most important branches of scientific research. Consequently Slavic philology, history and natural sciences were studied, and these soon reached European academic levels.

The founder of Czech and Slavic philology, Josef Dobrovský (d.1829), was also a founder of modern critical rationalistic methods of research rooted in the Enlightenment. Bernard Bolzano, the greatest philosopher of this era, developed on the traditions of the Enlightenment and criticized Kantian and post-Kantian philosophy. An inventive mathematician and one of the founders of the philosophy of science and modern logic, he investigated the semantic basis of logical systems. His pursuit of the relationship between idea (*Vorstellung*) and notion, of the notion of consciousness, and of the function of *Vorstellungen* in a sentence, was later expanded by Husserl (see Husserl, E. §6). Jiří Procházka (d.1820), a physiologist, initiated the reflexive theory of spiritual activity. (His 1784 essay *De functionibus systematis nervosi commentatio* was translated into English in 1851, and influenced the theory of Marshall Hall.) Later on, in the spirit of German *Naturphilosophie*, he created a dynamic picture of nature according to the law of polarity derived from the science of electricity. Jan Evangelista Purkyně (d.1869) was also influenced by the German tradition. A founder of the theory of cellular construction of living organisms, he added a historical dimension to his dynamic concept of nature, and held a pantheist ontology (see Pantheism). František Palacký (d. 1876), author of the monumental 'History of the Czech nation', had pursued philosophy in his youth. He was influenced by neo-humanism, and especially by Schiller on whose ideas he formed a model of perfect humanity and thus his humanistic philosophy of Czech history, which for a long time was a basis for Czech policy (see Schiller, F.C.S.).

The revolution of 1848 was philosophically reflected in the work of Augustin Smetana (d. 1851), whose roots were in left-wing Hegelianism. In his philosophy of human spirituality he created an independent variant on the philosophy of identity, based on the relative identity of knowledge (*Wissen*) and existence (*Sein*). He interpreted the Hegelian historical scheme of the development of *Weltgeist* so that it envisaged that the era to come would bring a dominant role and social justice for the Slavs. However, the impact of Hegel's philosophy was not very strong in Bohemia.

The dominant trend in philosophical thinking in the second half of the nineteenth century in Bohemia was Herbartism, introduced to Bohemia by Franz Exner (d. 1853) who opposed Hegel's idealism and criticized his psychology (see Herbart, J.F.). Robert Zimmermann (d. 1898), a student of Bolzano, managed to influence this trend through his historic and synthetic works in aesthetics while working at Prague University. Some followers of Herbartism developed single philosophical disciplines, others originated completely new ideas in the philosophy of religion, the history of philosophy, sociology, social psychology, and logic. Otakar Hostinský (d. 1910) created an aesthetic concept of 'concrete formalism' and the philosophy of art, and some of his ideas were employed by the Prague structuralist school (see Structuralism in linguistics). Herbartism was very influential throughout central Europe, and to some extent it fulfilled the role of positivism in Czech intellectual life (that is why classical positivism appeared relatively late; but it lasted well into the twentieth century). Herbartism tried to react positively to impulses from contemporary sciences (empirical psychology and Darwinism for example) and provided the first steps to a variety of new concepts and inventions such as *Gestaltqualitäten*, the neopositivism of the Vienna Circle, and the relationship of consciousness and subconsciousness in Freud (see Vienna Circle).

Miroslav Tyrš (d. 1884) stood outside this trend. He transformed Schopenhauer's pessimistic concept of the will into a philosophy of human activity of a subject who is both a counterplayer and a co-player in the struggle of life (Darwin's influence) and formulated a new plan for the development of a small nation, working it out in practical terms by founding a mass physical training organisation 'Sokol' which is still in existence (see Schopenhauer, A.). Tomáš Garrigue Masaryk began his philosophical career by opposing Herbartism and German post-Kantian philosophy, and he gradually succeeded in weakening their positions. His philosophical roots were in French and English positivism, but he used these solely as a research methodology to investigate the general crisis of values. He sought to resolve this crisis by using the concept of a human being as a harmonious unity of reason, will and emotion. His thought was based on religious values of the Czech Reformation and on the idea of democracy, understood as a humanistic world outlook. After 1918, this concept became the central idea of the newly formed Czechoslovak state, of which Masaryk was the first president.

3 From the foundation of an independent state

The culture and political climate of the new democratic state was conducive to philosophical investigation, and philosophy was an integral part of the curriculum in the newly formed universities and colleges. Among the many trends, positivism was still in fashion and even became a sort of national philosophy. It was mostly true to J.S. Mill's principles of positive methodology and to Comte's schemes of development, although attempts were made to modernize these (see Comte, A.; Mill, J.S.). Josef Tvrdý (d. 1942) introduced the emergentism of Samuel Alexander to the qualitative understanding of evolutionary processes. However, Josef Král (d.1978) worked out his concept of the history of Czech thought in a traditional spirit. Emanuel Chalupný (d.1958) also pursued the philosophy of Czech history and created his own sociological system. Spiritual fathers of neo-positivism like Ernst Mach (a long-serving professor at Prague University), Rudolf Carnap and Philip Frank, who both worked in Prague for some time, had less direct impact on Czech philosophy.

Masaryk's humanistic philosophy based on religion was adopted mainly by Protestant thinkers, including Emanuel Rádl (a proponent of 'intuitive realism' and critic of positivist scientism), Josef L. Hromádka (an independent follower of so called dialectic theology), and Jan B. Kozák (who was influenced by phenomenology and attempted to solve the problems inherent in the relationship between science and belief, and the question of objective ethical values). Masaryk's influence extended into many different fields and he found followers in a wide range of disciplines.

In the period between the First and Second World Wars, the three basic streams of structuralism, phenomenology and non-orthodox Marxism constituted mainstream philosophy, and their impact was to prove of major importance. About 1930, structuralism became a methodological basis for some of the humanities and social sciences and took a specific dynamic form with an expressive historical aspect. Its noetical, ontological and sociological principles were worked out by Josef Ludvík Fischer who also created a model of structural democracy, freeing all social forces for the benefit of the individual and society as a whole. Theoretical bases for sociology were formed in an analogical way by In. Arnošt Bláha. The *Cercle linguistique de Prague* became an internationally acclaimed propagator of the structural and functional understanding of language, literature and the arts, enriching the philosophy of all three in the works of Jan Mukařovský and Roman Jakobson. Additionally, structural philosophy of education and structuralist methods in psychology were advocated by Václav Přihoda (see Structuralism).

The Czech-German *Cercle philosophique de Prague*, founded on the initiative of the aesthetician Emil Utitz, with J.B. Kozák, became an ideological centre of the phenomenological movement. In 1935 Husserl was invited to Prague and the lectures he delivered were the basis for his final book *The Crisis of the European Sciences*. Jan Patočka, Husserl's pupil, became the most important representative of phenomenology in Bohemia. In the 1930s he worked on the problem of the original, predetermined natural world (*Lebenswelt*), its structure, and the activity of human beings in it. This was a very progressive project and it was some time before it gained a following in the phenomenological literature. Also some structuralists of the era had an interest in phenomenology and duly modified their concept of the function and tasks of art in the context of human existence (see Phenomenological movement).

Marxist philosophy in the first half of the twentieth century had a social basis in a strong left-wing political movement. Apart from the ideologists who took their starting point from the Communist Party, there were those

who took Marxism as a starting point for independent thinking. One such thinker was Karel Teige, an important theoretician of avant-garde art. He regarded artistic activities a means to realize an ideal of a free human being and to apply his creative force in the contemporary social conditions. Jaroslav Kabeš, who was influenced by the young Marx and later on by great representatives of Czech culture, persisted in questioning the purpose of human existence. The problems of a materialistic concept of history, and particularly its relation to Czech history and the history of European revolutions, attracted the attention of Kurt Konrad and Záviš Kalandra. The latter was also one of the first Czech Marxists to consider the importance of Freud's work in understanding the role of the psychological factor in history and the structure of personality.

Other philosophers of the first half of the twentieth century also had significant influence and impact. They include Ladislav Klíma, a radical subjectivist and philosopher of free existence in an absurd world, anticipating later existentialism (see Existentialism); natural scientists František Mareš and Karel Vorovka who argued against positivistic scientism from an idealistic starting point; Vladimír Hoppe who emphasized intuitivism and mysticism; and Karel Engliš who created a philosophical system based on the teleological understanding of social relations (see Functionalism in social science). Among Catholic researchers, neo-scholastic Josef Kratochvil attracted most attention. He called his standpoint 'neo-idealism' and aimed to overcome the positivist view of unknowable transcendence. The group of philosophers and theologians gathered around the journal *Filosofická Revue* was also neo-thomistically oriented, while those German philosophers in Prague who gathered round the Brentano-Gesellschaft, formed from the second generation of Brentano's pupils, were also very active.

During the Nazi occupation and the following six years of the Second World War, the continuity of philosophical investigation in Bohemia was interrupted. Universities and colleges were closed down and severe censorship was introduced. Some important philosophical figures were executed, some imprisoned in concentration camps and others forced into exile. The end of the war did not mean a return to pre-war conditions, the shift towards socialism creating a new situation. In the relatively free political situation of the years 1945-8 the ideological influence of Marxism was increasing. This process was supported by Arnošt Kolman who came back from the Soviet Union, as well as by many philosophers of socialist orientation who accepted Marxism and those who had previously been closer to it. Some non-Marxists continued to hold on to their former views.

This situation changed in February 1948 when the Communist Party came to power. Stalinism became the official ideology and all other philosophical and ideological schools of thought were prohibited. Many philosophers, especially Catholics, were imprisoned, and some of the younger ones left the country. Marxists were also persecuted. It took almost ten years for the ideological opposition to get more space for freer philosophical investigations. Meanwhile, Masaryk continued to have followers at home and abroad, Fischer continued his ontological work based on structuralism, and Patočka proceeded in his phenomenological investigations, trying to synthesize his ideas with those of Heidegger, while also maintaining an interest in the history of philosophy.

In the 1960s, young non-Marxist intellectuals gathered round the cultural journal *Tvář (Face)* - its spiritual agent was a playwright, Václav Havel, and philosophical essayists Ladislav Hejdánek and Jiří Němec were among the contributors. The freer atmosphere was also favourable to the development of non-orthodox Marxism, and the tendency to integrate elements of contemporary European thinking with Marxism became stronger, manifesting itself in many ways. An important experiment aimed at solving phenomenological-existential problems on the basis of Marxism was carried out by Karel Kosík, and similar efforts were made by other philosophers of the same generation. Questions of philosophical anthropology and ethical study also attracted attention. The problems of structuralism and the philosophical message of the artistic avant-garde were considered using Marxist categories by Robert Kalivoda (d. 1989) and simultaneously by other theoreticians in different variants. Other philosophers researched analytical philosophy, cybernetics, semantics and modern logic. In this connection are works written by Ladislav Tondl, Otto Weinberger and Pavel Tichý. At this time, much light was shed on the many periods of the history of philosophy, including that of Bohemia, while at the same time systematic questions raised by the material were widely discussed.

The third catastrophe of Czech philosophy in this century was the defeat of the 'Prague Spring', and the subsequent inauguration of another totalitarian regime. The majority of philosophers in the movements discussed above were dismissed from their posts at universities and research institutions, were prohibited from publishing and their books were removed from public libraries. Those who did not leave the country were compelled to work

as unskilled manual workers. This gave rise to vigorous unofficial intellectual activity. In spite of police repression, lectures and seminars were organized in private houses, sometimes with the participation of philosophers from France, England, Germany and The Netherlands. Dozens of books and some magazines were issued independently (*samizdat*), and many works were published abroad. This situation was not without precedent - the philosopher and poet known as Egon Bondy (real name Z. Fišer), a legendary personality of the Czech underground, had been involved in such activity since 1948. Students of Patočka took part in the preparation of a twenty-seven volume edition of Patočka's Collected Works, and the youngest generation of his pupils continued in his tradition after their teacher's death. This time also saw the formation of an active group of Catholic-orientated philosophers who concentrated their efforts on publishing the illegal magazine *Paraf* (whose name derived from *Para*lelní *f*ilosofie, parallel philosophy, in opposition to the official philosophy). In the 1980s, as the pressure of the regime gradually decreased, many (mostly younger) philosophers were given the opportunity to work in the official institutions.

The fall of the totalitarian regime at the end of 1989 allowed the necessary conditions for the resumption of Czech philosophy to be re-established. Such freedom had existed in modern times only in the period between the two world wars. Many philosophers of the older generation returned to their original profession, as did some younger philosophers who had been forbidden to work in their field of study after graduating. E. Kohák, I. Sviták, J.M. Lochman and K. Chvatík were some of the philosophers living in exile who now renewed contacts with home. Besides these there was the Catholic thinker M. Loblowicz, analytic philosophers and logicians O. Weinberger, P. Tichý and J. Šebestík, phenomenologist I. Šrubař, postmodernist V. Bélohradský and others. Active philosophical life could now resume.

D’Alembert, Jean Le Rond (1717-83)

Mathematician, scientist and man of letters, Jean D’Alembert is a central figure of the French Enlightenment. As a young man he made significant contributions to the refinement of mathematical techniques, and later was actively engaged in the theoretical controversies which surrounded the gradual assimilation of Newtonian mechanics into the mainstream of European science. For twelve years (1746-58) he was co-editor, with Denis Diderot, of the Encyclopedia, the serial publication of which was one of the defining events of the Enlightenment period as a whole. D’Alembert frequented the various Paris salons where much of the intellectual fervour and high-spiritedness of the age was cultivated and given shape. As Secretary of the French Academy he worked assiduously to advance the cause of human knowledge.

D’Alembert’s philosophy is characterized by an abiding commitment to the clarity and precision which attends mathematical abstraction. He believed that in its essence the natural order is internally structured by laws whose operation can be articulated under the principles of geometry. All natural phenomena are to be explained under the terms of those basic mathematical principles that govern the scientific domain in which they are located (chemistry or astronomy for example), and all scientific domains could be brought ultimately to perfect consistency and systematic order within a comprehensive theory. The events and processes which constitute the natural order reflect the reality of the mathematical structure which underlies them. As he says in the Preliminary Discourse (1751) to the Encyclopedia (1751-65), ‘The universe would only be one fact and one great truth for whoever knew how to embrace it from a single point of view’.

1 Life and works

D’Alembert was the illegitimate son of Mme de Tencin and the chevalier Louis-Camus Destouches. Shortly after his birth he was left by his mother at the steps of the church St Jean Le Rond in Paris, a circumstance which gave the boy his name. While never formally acknowledging paternity, the father took a devoted interest in his son and provided for his education. Jean was enrolled in the Jansenist Collège des Quatre Nations under the name of Dalemberg, which was later altered to the form by which he is known to history. The boy’s intellectual gifts were apparent from the start; he was encouraged to pursue a career in theology, though he never expressed any great interest in it, studied law and medicine for three years, but was increasingly drawn to mathematics. Though his formal instruction in mathematics was limited, by 1739 D’Alembert had attained a sufficient mastery of the subject to submit a paper to the Academy of Sciences in which he pointed out some errors in a popular textbook of the time. On the strength of this and several other mathematical papers he was elected to the Academy of Sciences in 1741.

In 1743 D’Alembert published his *Traité de dynamique (Treatise on Dynamics)*, a book which attracted the attention of the leading scientific authorities and helped secure his reputation as a most promising young savant. In this, his first major publication, he attempted to reconstruct the science of motion (mechanics) on a purely formal and mathematical basis, proscribing appeals to any such quasi-metaphysical notions as force or gravity and assigning observation and experiment to the subordinate role of confirming the basic principles of the theory. The axioms of geometry, together with the assumption of the impenetrability of the objects constituting a system, were all that was needed to establish the precision and certainty that should attend the study of motion. By this time Newtonian mechanics was well on its way toward gaining the ascendancy over the vestiges of Cartesian physics, and D’Alembert was in compliance with the best scientific opinion of the day in rejecting Descartes’ theory of vortices and his conception of nature as a plenum. In certain fundamental respects, however, D’Alembert retained a decided preference for a rigorous, Cartesian rationalism in his approach to scientific theorizing as opposed to the meticulous empirical observation and data-gathering which characterize Newton’s own researches (see EMPIRICISM; RATIONALISM). For D’Alembert priority should always be accorded to the strict logical formulation of the basic principles which grounded any scientific inquiry, and he maintained that such principles could be articulated independently of experience. While many of his contemporaries were impressed by the extent to which D’Alembert had apparently succeeded in preserving and carrying through to completion the best features of the Cartesian approach to physical science, others raised the suspicion that his attempts to mathematicize the foundations of mechanics were based on a confusion regarding the ineluctably empirical dimension of basic mechanical principles. In any case, the *Traité de dynamique* is secure in its place in the history of science for

having clarified the central theoretical issues which remained to be addressed in working out the details of the Newtonian programme, preparing the way, in particular, for the later researches of Lagrange (see DESCARTES, R.; NEWTON, I.).

Over the next few years D'Alembert produced a series of scientific monographs in which he applied the principles worked out in the *Traité de dynamique* to specific problems including the behaviour of fluids, the cause of the winds, precise calculations for the incidence of the equinoxes and the vibration of strings, all impressive scientific achievements in their own right. Beginning in 1746, however, D'Alembert's intellectual energies began to move away from such narrowly focused scientific investigations towards a more literary engagement with the broader currents of the Enlightenment movement that were gaining momentum across Europe. This year marks D'Alembert's earliest involvement in the tempestuous history of the publication of the *Encyclopedia* which he was to co-edit with Denis DIDEROT for the next twelve years. In 1751 he produced the *Preliminary Discourse* to the *Encyclopedia*, the work for which he is best known; he would ultimately contribute, or make substantial editorial additions to some 1,500 articles on an enormous range of topics from mathematics and physics (which make up the largest part of his contribution) to music, philosophy and religion. In many of these articles D'Alembert is unabashedly partisan in his support of the philosophical campaign to secure the claims of science and enlightenment against the resistance of the political authorities and the chauvinism of the religious establishment. By his polemical zeal, for example, in his contentions against the unflagging hostility of the Jesuits to the whole *Encyclopedia* project, he makes known his willingness to be counted among the ranks of the *philosophes* who, in turn, were more than happy to have his considerable reputation as a scientist joined to their cause. The depth of D'Alembert's commitment to the cause was challenged, however, when his article 'Genève' appeared in 1757 in the seventh volume of the *Encyclopedia*. He had intended to present a flattering view of the atmosphere of religious tolerance in Geneva at the time by imputing to the authorities there an advocacy of various doctrines associated with SOCINIANISM, such as the denial of the divinity of Christ. The Genevans were neither flattered nor amused. In the firestorm of criticism and vituperation that came down on his head in the months after his article appeared, D'Alembert resigned his position as editor and withdrew from the public controversies altogether, much to the disappointment of his more vociferous comrades including, notably, Voltaire. His further contributions to the *Encyclopedia* would be confined to relatively uncontroversial topics dealing with scientific matters with which he was especially conversant.

In 1754 D'Alembert was elected to the French Academy, and if the high profile and protracted controversies of the *Encyclopedia* project were too much for D'Alembert's tastes, his membership in the Academy provided the ideal setting for his continued advocacy of the natural sciences. For some years prior to his election, the reputation of the Academy had been diminished in the public's estimation by the perception that its members were perhaps too much beholden to the interests of the political establishment. With D'Alembert things changed. By virtue of his own reputation for scholarly achievement and personal integrity he was able to improve contacts with scientific establishments across Europe and cultivate friendly relations with foreign heads of state. Internally, he worked assiduously in the cause of progressive ideas by setting agendas and seeking to advance the careers of like-minded colleagues. In his speeches before the assembly and public addresses he championed the cause of the philosophic spirit and argued the material and moral advantages to a society in which it was permitted to flourish. In ways that were unprecedented he brought the affairs and proceedings of the Academy before the public and thereby enhanced the reputation of the Academy itself while raising at the same time the status and the influence of scientific and philosophic research. In 1772 he acceded to the office of permanent secretary of the Academy in which capacity he continued to serve until his death.

Throughout this period D'Alembert continued to write and publish books and essays on scientific and philosophical topics. In 1759 he published the *Essai sur les éléments de philosophie*; in the aftermath of the Jesuit expulsion from France in 1762 he published the highly polemical essay *Sur la destruction des Jésuites en France* (1765), in which he argued, in effect, that it was the rising tide of enlightenment which precipitated the downfall of this remaining bastion of religious obscurantism. His technical works in mathematics and physics were published in eight volumes as *Opuscules mathématiques* between 1761 and 1780. His voluminous correspondence, his many speeches and elegies were collected and published posthumously.

2 Philosophical outlook and the *Preliminary Discourse*

D'Alembert, Jean Le Rond (1717-83)

D'Alembert's philosophy is of decisive importance to anyone who would understand the Enlightenment in its intellectual and theoretical (as distinct from its social and political) dimension because it manifests, more clearly perhaps than any other author's, the delicate combination of French rationalism in the tradition of Descartes and Malebranche and British empiricism as represented by Newton and Locke (see Malebranche, N.; Locke, J.). As a mathematician of the very first rank, D'Alembert was entirely sympathetic to Descartes' insistence upon the clarity and precision of basic principles and the need for rigorous deductive logic in establishing the linkages between one theoretical proposition and any others which might be linked with it. Like virtually all his contemporaries, D'Alembert was hugely impressed by the power of Newtonian mechanics to explain and integrate vast tracts of natural phenomena and predict future events, and by the extent to which observational and experimental data could be incorporated into a system constituted at its core by mathematical principles. To understand D'Alembert himself, and to appreciate his importance as a signal representative of the thought of this watershed period in human history, the relationship between the Cartesian and empirical strands of his work must be made out.

D'Alembert was unequivocal in his rejection of metaphysical principles as constituting an appropriate base for inquiry in the natural sciences. He repudiated the Cartesian doctrine of innate ideas and denied that Descartes' *Cogito* had any value as a starting point in constructing the system of human knowledge. Appeals to divine intervention in the natural order had no place in trying to explain the connection between events or the relation between natural objects and the human perception of them. In this respect, D'Alembert adhered closely to the principles of Lockean epistemology as these were modified and expanded in the works of his friend and colleague, CONDILLAC. With Locke and Condillac, D'Alembert insisted that all knowledge begins by attending to the facts and that the way those facts *appear* to us is as close as we can ever hope to get to their reality. But the facts which present themselves to our experience are only isolated and fragmentary pieces of a greater systematic structure in which they are embedded, and for the full articulation of that structure one must have recourse to the principles of mathematics - specifically those of geometry - in order to represent the orderliness of natural events and processes. The basic principles of any science should consist in perfectly unambiguous and precise mathematical formulas together with whatever basic assumptions are necessary to secure their attachment to the objects which constitute the domain under investigation. The various discrete facts disclosed to our observations can then be expressed as formal propositions which could in turn be fitted into the deductive chain of formulas derivable from the basic principles.

D'Alembert rejected Descartes' notion of the universe as a plenum because it was infected by the unwarranted metaphysical doctrine of substances. In his own conception of the universe, however, D'Alembert maintained that all parts of nature are systematically interrelated in a comprehensive structure of laws which evinces the same integrity, consistency and formal precision as any of the more extended and elegant proofs in geometry. Like Descartes, D'Alembert believed that the methodical and painstaking implementation of human reason would gradually serve to disclose this rational structure, and that, as it came into view, the empirical facts could find their place within it and thereby attain theoretical clarity. By setting his first priority on the articulation of the rational structure which informed all of nature, D'Alembert comports with the most fundamental aspects of Cartesian methodology and reaffirms the optimistic faith of his great precursor in the autonomous power of human reason.

In the *Preliminary Discourse* to the *Encyclopedia* D'Alembert presents an interpretation of the contemporary state of scientific research in which his own rationalistic conception of the structure of human knowledge forms the core. The *Encyclopedia* itself is conceived as a compendium of all the scientific truths so far achieved, but the greater utility and value of the work is found to consist precisely in its capacity to arrange and integrate these results so as to facilitate further research by revealing both the systematic interrelations between seemingly remote domains and the lacunas which remained to be filled in. D'Alembert compares the *Encyclopedia* to a road map: certain areas of the terrain of human knowledge are well understood and laid out in careful detail while the expanses between these areas are marked out only by the most rudimentary traces which might none the less provide a researcher with his theoretical bearings as he laboured to extend the boundaries of knowledge ever deeper into the realm of *terra incognita*. All of the articles in the *Encyclopedia* were to be knit together by an extensive network of cross-references so that an arbitrarily selected topic would lead the reader eventually to a comprehensive view of the whole structure in all its intricacies. The *Encyclopedia*, as the systematic embodiment of the whole vast range of human knowledge, would thus reflect the rational structure which constituted the natural order itself.

D'Alembert invokes a second metaphor in the *Discourse*, inspired by the prescient writings of the great English philosopher of science Francis Bacon, in which the 'tree of human knowledge', rooted in such fundamental disciplines as mathematics and logic, branches out into the various scientific subregions and extends ever further to include the most narrowly defined and detailed subject matter. Reconfiguring the Baconian conception of knowledge in accordance with the general principles of epistemology worked out by Condillac, D'Alembert recognizes three essential functions of the human mind: memory, reason and imagination. Under these three rubrics all domains of human inquiry, including history (sacred, civil and natural), literature and art, can be systematically interrelated. This second metaphor expresses D'Alembert's view of knowledge as an organic unity, as something which grows from within when all of the various parts derive their sustenance from the flourishing of the others and contribute in turn to the flourishing of the whole.

To D'Alembert's way of thinking there was no area of human inquiry which could not be incorporated into this unified and integrated structure of knowledge, and in this respect the *Preliminary Discourse* gives powerful and eloquent expression to one of the guiding inspirations of the Enlightenment period as a whole. In his own researches he made significant contributions toward bringing the study of language and aesthetics under the purview of science, and believed that ultimately even politics and morality should have to be subsumed under its methodology if there were to be progress. But here, D'Alembert's attachment to rationalistic principles becomes deeply problematic, in that the more inscrutable and ambiguous aspects of human nature seem unamenable to anything like the geometrical precision that he made the hallmark of all true science. If from our historical vantage point his own philosophical commitments should appear somewhat dogmatic and unwarranted, we must at least acknowledge that the issues concerning the relationships between the various domains of human knowledge to which he was so acutely sensitive continue into our own day, reflected in the uneasy division within institutions of higher learning between the humanities and the 'hard sciences'.

3 Reputation and influence

D'Alembert continues to enjoy a rightly prominent role in virtually all historical treatments of the Enlightenment period. He is one of only a few *philosophes* to have achieved the very highest standing as both a scientist and man of letters. His contributions to mathematics and physics stand as significant landmarks in the history of both disciplines. His indefatigable labours as secretary of the French Academy were profoundly efficacious in advancing the cause of enlightenment across Europe. Some of the most important historical figures of the age, including Voltaire, Frederick the Great and David Hume were proud to count him among their friends, a testament to both his high reputation and the warmth and integrity of his personality. His philosophical work was influential in the world of practical affairs as well, for example, in the formation of economic policy under the ministries of Quesnay and Turgot. And it is by no means the least of his contributions to have served as mentor to and helped to advance the careers of some of the brightest young minds of the rising generation such as Laplace, Lagrange and Condorcet. A close study of D'Alembert's life and works provides an excellent point of entry into the world of the European Enlightenment.

Dai Zhen (1724-77)

Dai Zhen, a neo-Confucian philosopher, argues against the received neo-Confucian view of dao *as a metaphysical entity. On the contrary,* dao *is immanent in the world and, in the case of the human world specifically, in the everyday lives of ordinary people irrespective of social status. His philosophical views had important political and social implications.*

Dai Zhen came from Huizhou in Anhui Province. During his early years, Dai often accompanied his father, a cloth merchant, on business trips which brought him in touch with the political and social realities in many parts of China. In 1754 he became entangled in a lawsuit with a powerful clansman who was a friend of the local magistrate and, on being informed that he was about to be arrested, left home in great haste and went to Beijing. This background exerted no small influence on the formulation of his philosophical critique of the dominant Confucian ideology in decades to come.

Dai wrote three important philosophical treatises: *Yuanshan (Inquiry into Goodness)*, *Xuyan (Surviving Words)* and *Mengzi ziyi shuzeng (Commentary on the Meanings of Terms in the Book of Mencius)*. A central concern of all his writings is the immanental status of *dao*. He contends by way of etymology that this is the original meaning of *dao* in early Confucian texts. Understood analytically, *dao* consists of all the principles or patterns (*li*) discoverable in the world. Song dynasty neo-Confucians are wrong, due to the influence of Buddhism, in assuming that *li* is a gift from Heaven and resides in the human mind/heart as if it were a thing. Viewed objectively, *li* is none other than the internal texture and structure in things (see Dao; Li).

True to Confucian humanism, Dai makes an important distinction between what is natural (*ziran*) and what is necessary (*biran*). The former refers to principles or patterns governing all the activities in the world whereas the latter refers to those in the human world exclusively. In this view, not only is the human world continuous with the natural world but the two worlds are also marked by a clear break, thereby distinguishing human beings from all other kinds of beings. He understands the idea of goodness (*shan*) in this light. In his own words: ‘Goodness is what is necessary whereas nature (*xing*) is what is natural (see Xing). What is natural will be fully completed only when it is developed into what is necessary. This is known as developing the natural to the utmost’ (*Mengzi ziyi shuzeng*: 195). This suggests that the world will not be complete without human beings.

Following the same logic, Dai rejects the neo-Confucian bifurcation between moral principles (*li*) on the one hand, and human desires (*yu*) and feelings (*qing*) on the other. Moral norms are capable of regulating human desires and feeling precisely because they are the internal texture and structure in the everyday life of human beings rather than something imposed on it from outside. His objectification of *dao* and *li* naturally leads him to emphasize the central importance of intellectual inquiry known as ‘investigation of things’ (*gewu*) in the Confucian tradition (see Neo-Confucian philosophy §9). Intellect or intelligence (*zhi*) is what distinguishes human beings from other phenomena (see Zhi).

Dai draws important political and social implications from his philosophical views. He believes that the neo-Confucian concept of *li* as Heavenly Principle always serves to justify the oppression of the helpless common people by those in power. The struggle of the common people to satisfy their basic needs in life are denounced as ‘selfish desires’ and anyone who has the audacity to defy the norm imposed on the common people by the ruling elite often ends up being condemned to a moral death. Clearly, he is deeply dissatisfied with the Song dynasty neo-Confucian definition of *li* as ‘heavenly principles’, which has been used by those in power to justify the oppression of the helpless common people. Thus in Dai’s philosophical system, we see an unmistakeable beginning of a modern spirituality uniquely China’s own.

Damascius (*c*.462-540)

The late Neoplatonist philosopher Damascius was the last head of the Platonist school in Athens. He largely accepted the metaphysical system of the Athenian School of Syrianus and Proclus, but subjected it to acute dialectical scrutiny in a series of commentaries, and especially in his treatise On First Principles. His philosophical position is not comprehensible without bearing in mind that of Proclus, although on certain issues, such as the nature of the first principle and of the soul, he prefers the solutions of the earlier Iamblichus.

Damascius was probably born *c*.462 in Damascus. He studied rhetoric first in Alexandria and then moved to Athens shortly before the death of Proclus in 485. He practised in Athens as a professor of rhetoric and, although he attended lectures in philosophy, he experienced a real ’conversion’ to philosophy only in around 491, under the influence of the Platonist Isidorus, whose life he later wrote. At about this time, following Isidorus, he returned to Alexandria for a spell, where he attended also the lectures of the Platonist Ammonius, son of Hermeas.

Around 510-15, Damascius himself succeeded as head of the Platonist school, and from then until 529 he presided over an intellectual and financial revival of that institution, which had fallen into some obscurity. His students included Simplicius (§§1, 3), who testifies to the acuteness of his intellect and the excellence of his instruction (*On Aristotle's Physics* 624.38).

In 529, the emperor Justinian issued his famous decree against non-Christian teachers. This effectively closed the Platonic school. In its wake (*c*. autumn of 531), following on the accession to the throne of Persia of the young Chosroes, who had a lively interest in philosophy, Damascius and a group of other philosophers decided to emigrate to Persia. They returned after a year, however, under a safe conduct arranged by Chosroes, which enabled them to philosophize in private. Damascius’ last years were probably spent at Emesa in Syria, where he died.

Damascius’ works are only partly preserved, and often in an unsatisfactory state. We have no surviving commentaries by him on Aristotle, but Simplicius, in his commentary *On Aristotle's Physics*, quotes extensively from a special treatise of his *On Number, Space and Time*. His commentaries on Plato have survived somewhat better, but even the surviving ones on the *Phaedo and Philebus* are in the form of students’ notes. His only properly surviving works are the treatise *Problems and Solutions on First Principles*, and his *Commentary on Plato's Parmenides*.

It is chiefly from these two latter works that we can appreciate the particular quality of Damascius’ philosophizing. Situated at what was effectively the end of a long philosophical tradition, he exhibits a remarkable blend of scholastic elaboration and critical acumen. He accepts all the metaphysical convolutions of Syrianus and Proclus, and those of Iamblichus before them. Indeed, one of his distinctive features is a tendency to revive positions of Iamblichus in opposition to those of the later Athenian School, as well as their penchant for syncretistic theology, and such documents as the Chaldaean Oracles and the Orphic Theogonies (see Chaldaean Oracles). In contrast, however, he rigorously puts all the basic principles of Neoplatonism to the test of dialectic, with most stimulating results.

There are four main topics examined in *On First Principles*. First, the nature of the first principle, in which Damascius examines the case for an absolutely ineffable principle prior to the One proper, while analysing the contradictions involved in postulating a first principle which is both entirely simple and transcendent, and the source of all creation and diversity. Second, an analysis of the components of the henadic realm, the triad of One-many (Monad), many-One (Indefinite Dyad) and ‘the unified’, which is the union of the two. Third, arising out of this, a penetrating discussion of the central dynamic of Neoplatonic metaphysics, the triple process of remaining, procession and return (*monē*-*proodos*-*epistrophē*). And finally, the relationship of the intelligible realm as a whole to its parts, the Forms. In his *Commentary on Plato's Parmenides* we find his views on the nature of the soul, which he sees as a radically median entity, subject to change even in its essence.

To ask what is distinctive in Damascius’ philosophy, however, results in a complex answer. His philosophy is unashamedly that of his predecessors. Where he differs from Syrianus and Proclus, as he does on such questions as the nature of the first principle and the economy of the henadic realm, or on the nature and status of the soul, he is often only reverting to the doctrines of Iamblichus. Even his views on space and time, and his postulation of

archetypal forms of both these entities, largely develop positions of Iamblichus. Damascius' particular genius lies rather in the dialectical analysis to which he subjects all these questions, and it is for this that he is valuable.

Damian, Peter (1007-72)

Peter Damian is noted for his asceticism, contributions to church reform and literary style, the latter in writings that are primarily religious in character. Because of his hostility to the unbridled use of the disciplines of grammar and dialectic in religious matters, Damian is sometimes depicted as an opponent of philosophy. A more accurate assessment of his attitude is that the liberal arts, including philosophy, must remain subservient to religion. Damian's major work De divina omnipotentia (On Divine Omnipotence) shows that he was willing and able to use philosophical argument in theology.

Peter Damian was born in Ravenna in 1007, entered monastic life with the Benedictine Order at Fonte Avellana around 1036, became prior in 1043, was made cardinal around 1057 and died in 1072. He was actively involved in monastic reform, writing opinions on such topics as simony, married clergy and sexual abuses committed by clergy. Damian's usual mode of writing was the epistle, of which some 180 survive, displaying considerable rhetorical skill on the part of their author.

Damian entered an ongoing controversy over the relation between secular learning - exemplified in the study of grammar, dialectic and philosophy - and divine revelation as contained in the Bible. Although he has sometimes been interpreted as a champion of anti-intellectual fideism, the attitude discernible in Damian's writings is more inchoate than the interpretation suggests. He believes that the Bible contains all the knowledge necessary for personal salvation, and that monks spend their time most profitably in its study. At the same time, however, in insisting that secular learning should be chastened and made subordinate to the study of the word of God, he seems willing to grant secular studies some legitimacy. He offers no delineation of what form that legitimacy might take. The debate about the relation between secular learning and revelation was soon to be subsumed under a larger debate about the respective roles of reason and faith in human understanding. Less than a generation after Damian's flourishing, for example, one can find more sophisticated observations in the writings of Anselm.

In a lengthy letter, now known as *De divina omnipotentia (On Divine Omnipotence)*, to Desiderius, Abbot of Monte Cassino, Damian displays his skills both as philosophical critic and theologian. The question to be determined is whether God's omnipotence includes the ability so to act that what has happened never happened. Damian criticizes Desiderius' claim that God is unable so to act because he does not will so to act. He thinks that Desiderius' claim amounts to (1) God does not will to do *A* if and only if God cannot do *A*, and argues that claim (1), along with the principle (2) God does *A* if and only if God wills to do *A*, entails (3) if God does not do *A*, then God cannot do *A*.

Claim (1) entails that if God does not will to do *A*, then God cannot do *A*. Principle (2) entails that if God wills to do *A*, then God does *A*. Since either God wills to do *A* or God does not will do to *A*, it follows that either God does *A* or God cannot do *A*, which is equivalent to (3). Because (3) means that God is able to do only what God in fact does, Damian thinks that Desiderius' claim (1) must be rejected.

Damian proceeds to offer two separate solutions to the original question. According to the first solution, it is true that everything that has happened necessarily has happened, but that fact is irrelevant to the issue of God's omnipotence. The sentence, 'everything that has happened, necessarily has happened', is trivially true, 'according to the order of speaking'. Although Damian lacked the terminological distinctions that later medieval philosophers had at their disposal, his point can be expressed in their terminology by saying that 'everything that has happened, has happened' is necessarily true *de dicto*, and is not to be confused with the *de re* interpretation, 'everything that has happened has happened necessarily'. Only the latter would impinge on God's omnipotence.

Damian's second resolution maintains that there is a way in which God can still bring it about that Rome, which was founded, never was founded. God lives not in time but in eternity, in which the temporal past, present and future are all equally present to God. Thus, according to Damian, the founding of Rome, although past from our temporal perspective, is eternally present to God's power. As such, God can still cause Rome not to be founded, a situation that we, living after the time of the founding of Rome, describe as God's power to cause Rome never to have been founded.

Dance, aesthetics of

The aesthetics of dance is the philosophical investigation of the nature of dance, of our interest in it, especially as an art form, and of the variety of aesthetic judgments we make about it - judgments of beauty, grace, line and other aesthetic qualities. Most philosophical issues concerning dance result from considering philosophical questions that arise in other areas: another art form, art in general, or human action. Sometimes the issue for dance can usefully be seen as a combination of issues from other areas. Often, one's response to such issues gives a possible direction for one's thoughts about dance.

A selection of such questions can be taken from the characteristics of dance. Since some dances are works of art, is there a kind of judgment characteristic of an interest in art, and, if so, what are its features? In particular, and in parallel with questions for other arts, does knowledge of the choreographer's intention have any role in understanding the dance? What follows for the understanding of dance from the fact that dance is a multiple art: that a particular dance (like a particular piece of music) can be performed in London at the same time as it is performed in New York? What follows from dance's status as a performing art (like music)? Is any special role for the understanding of dance to be assigned to a notated score in a dance notation? (If so, does this differ from music?) How is the special place of the dancer to fit into accounts of understanding dance? As some dances are regularly thought to be communicative, how does dance differ (if at all) from so-called 'nonverbal communication'? More generally, dance study must address far-reaching philosophical issues: the place of dance as human action; the 'role' of dance, for example, in ritual; the relevance of the history and traditions of dance-forms to the understanding of those forms.

1 Introduction

Dance has not been a major topic for philosophical enquiry for the contemporary aesthetician, because aestheticians have focused on problems in literature, music or painting, and because dance is viewed correctly as having few problems of its own: for example, discussion of the place of the choreographer's intention for criticism or understanding of his work will largely reproduce similar discussions for other artists (see Artist's intention) and theorists might be expected to take similar positions in both cases. Again, any discussion of dance must acknowledge that only some dances can be considered to be works of art, just as only some paintings are considered works of art. For dance, just as for other 'objects of aesthetic appreciation', aestheticians must ask whether the appreciation of art works is importantly different from the rest of 'aesthetic appreciation' or whether, instead, these cases should be understood in terms of one, underlying experience.

More specifically, the status of dance as a multiple art form, which allows the same dance to be performed in two or more places at the same time, and as a performing art are both shared by music. Thus, questioning the appropriateness of, for example, a type/token analysis for the relationship between the work itself and performances of it will be shared with the aesthetics of music, and it will be reasonable to expect analogous answers. Equally, issues resulting from the recording of dance using notation will be shared with those in music. This entry considers a selection from the many issues potentially lying within the ambit of the aesthetics of dance and provides remarks on each.

2 Dance, art and aesthetic appreciation

Does the philosophical aesthetics of dance concern only those dances or dance-forms that are, or could be, art forms, or should its net be cast more widely? In so far as its central interest lies in art-type dance, the aesthetics of dance will reflect concerns beyond the mere appreciation of grace, line, beauty and other aesthetic qualities in human movement. Then any value attributed to dance can begin from ascriptions of whatever value is proper to art, and issues in the aesthetics of dance will align with those in the aesthetics of other arts, especially other performing arts.

3 The distinctiveness of dance?

Dance is characterized by its *physicality*: it is an essentially physical art form and in this it differs from music, literature and visual art. Music and visual art require human action for their creation and existence, but the art objects are not physical (that is, not human action) in quite the same sense. Moreover, most dance - in contrast to

music - has a ‘mixed’ character: a typical dance performance involves not merely movement but costume, music, staging and the like. (In this respect, the typical dance resembles the typical opera.) What exactly are the roles of these other elements, some already having status as art? For example, attending the ballet *The Rite of Spring* involves hearing Stravinsky’s music. How is this to be integrated into our analysis of the art form? Of particular interest here are the ways in which elements of costume - often thought variable across different performances - can sometimes be entirely fixed by the choreographer, for example, in certain works by Alwin Nikolais. Equally, elements normally taken as fixed - for example, the music - may, in certain works, turn out not to be completely determined. For instance, Twyla Tharp’s *The Bix Pieces* (1971) has a variable musical element.

4 Dance as a multiple art and as a performing art

Dance and music share their performing character: one encounters the work of art itself only in some performance of it. So performing arts generate, as it were, two objects for discussion: the work itself and particular performances of it - *Swan Lake* itself and, say, Tuesday night’s performance of it. This fact has interesting implications. First, the dance itself is an abstract object - one never meets it, although, in another way, seeing the performances constitutes seeing it. Second, the dance can be seen in two places at the same time - by groups seeing different performances. So *Swan Lake* could be performed simultaneously in London and New York. Third, London’s *Swan Lake* and New York’s *Swan Lake* will differ, since they use different casts and are performed on stages of different sizes. In London, the producer may emphasize certain characteristics of *Swan Lake*, perhaps to suit the dancers in the cast. For similar reasons, different aspects may be stressed when the dance is staged in New York.

A type/token contrast (see Type/token distinction) that takes the work itself as the type and the particular performance as the token might be introduced here. Such an analysis would generate the three points noted above. Since *Swan Lake* is a type, it follows that it is an abstract object (the first point). As an abstract object, it is encountered only through encountering tokens: hence there can be more than one token at any particular time (the second point). But all the various performances are equally *Swan Lake*, despite their differences (the third point).

However, the type/token distinction cannot itself determine what is to count as a token of a particular type. There is a fine borderline between restaging a dance and re-choreographing to produce a different dance: for example, are some of Nureyev’s productions re-choreographed or merely restaged? This consideration recognizes a difficulty in deciding whether a particular performance is or is not a token of a particular type. For recognizing re-choreography as the production of a different work of art is a way of saying that its performances are tokens of a different type.

Three possible objections to a type/token analysis of dance illustrate the complexity of this issue. First, has the analysis identified the crucial elements? One might think that, as with music, the interpretation of the performer or of the stager was also of crucial importance: yet the proposed analysis leaves no room for it. Second, does the type/token contrast focus on the right characteristics of multiple art form or is Nelson Goodman’s autographic/allographic contrast more appropriate? (See Art works, ontology of §4.) Third, does the analysis tell us enough? Are we not still struggling to decide both when we have a token of a particular type and how the type ‘constrains’ its tokens?

5 Dance notation and understanding

One characteristic feature of dance as art is the possibility of its notation. There are three well-developed notation systems for dance: Labanotation, Benesh and Eshkol Wachman. Goodman has sketched the criteria of adequacy for any notation system for any art form: for example, the symbols must be clearly differentiated in order to pick out different states of affairs. One practical question is, ‘To what degree do the notation systems mentioned above fulfil such criteria?’ Alternatively, a philosophical issue arises concerning the uses to which notated scores might be put. Might they, for instance, play a role in the solution of (numerical) identity questions, such that any performance satisfying a notated score for *Swan Lake* was thereby bound to be an instance of that art work?

Two aspects of such notation systems have direct implications for the aesthetics of dance. First, dance notations radically under-determine the dance, by not guaranteeing that the movements they describe are dance rather than something else; by telling us nothing about costume, staging, music and the like; and by not fully determining the

movements to be performed. Notated scores embody perceptions of the movements in question. The movements are objects that have been analysed, in the choice of what are to count as the key characteristics of a particular pattern of movement, and are not potential objects for analysis. So notation systems offer *interpretative* descriptions rather than neutral documentations of movements. Second, recording a particular dance in different notation systems imposes different sets of constraints on the dancer. The two recordings might be satisfied by slightly different sequences of movements. For instance, a performance which satisfied a notated score for *Swan Lake* in Labanotation might fail to do so for a score in Benesh, and vice versa. All that can be urged is that only reputable notation systems count here: those knowledgable about an art form decide what is reputable.

Further, positive use of the phrase ‘those knowledgable about a particular art form’ is an admission that, in the end, it is a matter for judgment by dance critics whether or not something is an instance of a particular work of art. If Nureyev’s changes mean that his production no longer satisfies a particular notated score for *Swan Lake*, one alternative would be to doubt the appropriateness of that notation. It may, then, be a matter for art criticism, or more precisely for the critics of dance, whether a particular performance genuinely counts as a performance of *Swan Lake*.

6 The role of the dancer

The aesthetics of any performing art must address the role of the performer. The choreographer is the central artist, yet dancers should not be considered mere puppets of the choreographer, even when they have not been specifically involved in the initial creation of the particular dance. (As dances can typically be performed at a later date, there is an inherent possibility of dancers performing previously choreographed pieces.)

Revealingly, the term ‘interpretation’ is used in two distinct ways in performing arts, which I shall call ‘critic’s interpretation’ and ‘performer’s interpretation’. The first characteristically consists of strings of sentences that discuss the structure and value of the work in question. But a pianist’s rendering of a particular piano piece is also an interpretation. Here interpretation typically consists of some set of actions that are performed in producing the witnessable work. For dance, it consists in performing (at least) movements of the body. This second sort - performer’s interpretation - is unique to the performing arts, while critic’s interpretations are possible for all works of art. So any problems we have in understanding the idea of critic’s interpretation, or in seeing the basis of such interpretation are problems for all the arts equally. But concerns about making the interpretation an interpretation of a particular work of art, and of no other, and about ruling out inappropriate interpretations, have two dimensions for the performing arts. They apply not only to critic’s interpretation - a difficulty shared with other art forms - but also to performer’s interpretation.

When one witnesses a work in the performing arts, it has already become a performer’s interpretation. Works in any performing art are under-determined at their creation just as they are under-determined by their notations: they are only brought to determinacy by performance. In this sense, works in the performing arts typically come as recipes, with an instruction to perform them - an instruction to produce a performer’s interpretation. But once that interpretation is complete, the dance in that performance is determinate, and hence in the same position as works of the particular object sort, or non-performing works of the multiple sort, such as works of literature. Each has a physical instantiation which is available for critic’s interpretation and such critic’s interpretation will draw on the traditions and conventions of that art form. One important function of the dancer is thus as the creator of the performer’s interpretation. We can therefore understand the virtues of one dancer over another in terms of their respective abilities to produce interesting and sustainable performer’s interpretations.

7 Verbal and nonverbal communication

The distinctiveness of dance’s expressive character seems to have no parallel in music, and so requires different treatment. How, if at all, does the expressiveness of dance relate to the more general expressiveness of bodily movement: to so-called ‘nonverbal communication’? For the ‘instrument’ of dance is that very same human body in which we recognize, for instance, the sadness of another person through their posture, their words, and so on.

Activities that embody the intention to communicate can be distinguished from those that do not, even though actions of the latter type can teach us something about those who perform them - for example, their state of mind. Such a contrast, if sustainable, clearly places much dance, with verbal language and sign language, in one

category, and much else that is nonverbal in the other. If we distinguish art-type dance from dance that is not art, then any expressive or communicative power of the latter would be that of ‘other movement’. But should the expressive and communicative power of art-type dance be treated in the same way? If we conclude that it should, we have scarcely any reason for drawing the distinction between our interest in art and that in non-art. This in turn has implications for the value of dance, and in particular its educational value.

8 General philosophical issues

Finally, a significant number of general philosophical questions raise important issues for the aesthetics of dance. For instance, dance is a kind of human action: but how should we recognize or value, if at all, the dances of chimps or, in the future, of robots? Tentative solutions to various problems in the philosophy of action may be needed before events can be adequately characterized as dance at all, especially given the diversity of dances. Again, considering ‘dance in other societies’ raises a number of familiar questions concerning the beliefs of other cultures or societies. For instance, having recognized that the North American Indian ghost dances have a specific purpose (namely, to rid the continent of the white man), we will have difficulty concluding that they are art; can we even conclude that they are dance? For philosophical purposes the issue differs little from questions arising from, say, the Lascaux cave paintings.

As with other art forms, a developed aesthetics of dance would explore both the history of dance, at least as an art form, and the history of dance criticism. Thus, the question will arise of when it is appropriate to date the beginnings of dance. Should we, in parallel with Kristeller’s work on the concept ‘art’, think of art-type dance coming into being with the baroque ballet in, say, the court of Louis XIV? Or should we conclude that, since the Greeks had a muse for dance (Terpsichore), there must have been art-type dance in classical Greece? Resolving such questions is partly a matter for history, but also calls for philosophical reflection on the implications of calling the activity *dance* rather than something else.

Dao

Dao, *conventionally translated 'the Way', is probably the most pervasive and widely recognized idea in Chinese philosophy. The specific character of Chinese philosophy arises because a dominant cultural factor in the tradition, now and then, has been the priority of process and change over form and stasis, a privileging of cosmology over metaphysics. That the Yijing (Book of Changes) is first among the Chinese Classics in every sense bears witness to the priority of cosmological questions - how, or in what way (*dao*) should the world hang together? - over metaphysical and ontological questions - what is the reality behind appearance, the Being behind the beings, the One behind the many, the true behind the false? The contrast lies in finding a way rather than seeking the truth.*

To contrast the difference between the search for metaphysical 'truth' - the way things really are - and the mapping of an appropriate and productive 'way' (*dao*) in the human world, we might consider the philosophical questions being asked by representative texts. The project in the Confucian *Analects*, for example, is not to speculate on *what* the ultimate source of value in the world might be, but to recount biographically *how* one sensitive person, Confucius, made his way in the world as a possible model for others (see Confucius). The *Daodejing* does not purport to provide an adequate and compelling description of what *dao* and *de* might mean as an ontological explanation for the world around us; rather, it seeks to engage us and to provide guidance in how we ought to interact with the phenomena, human and otherwise, that give us context in the world (see Daodejing). Likewise the *Yijing* is not a systematic cosmology that seeks to explain the sum of all possible situations we might encounter in order to provide algorithmic insight into what to do, but is a resource providing a vocabulary of images that enable us to think through and articulate an appropriate response to the unique and always changing conditions of our lives (see Yijing).

Although the way of living to be discovered in the canonical texts, the *dao*, has historical antecedents, it is not simply to be discovered and walked. As the *Zhuangzi* 2 says, 'The path is made in the walking of it' (see Zhuangzi). *Dao* means both to lead along a path, and to be led along it. In the Confucian *Analects* 15.29 we read, 'It is the human being that can broaden the way (*dao*), not the way that broadens the human being'. The human being must be a roadbuilder because human culture - the human *dao* - is always under construction.

The parts of speech which order Western languages - nouns, verbs, adjectives and adverbs - encourage us to divide up the world in a culturally specific manner. Under the influence of these grammatical determinants, we are inclined to separate things from actions, attributes from modalities, where from when and when from what (see Syntax). However, given the fluidity between time, space and matter assumed in classical Chinese cosmology, these categories do not govern the way in which the world is divided. The categories used to define a Chinese world must be seen as crossing the borders of time, space, and matter. *Dao* is both 'what is' (things and their attributes) and 'how things are' (actions and their modalities). *Dao* has as much to do with the subjects of knowing and their quality of understanding as it does with the object of knowledge and its attributes. There are no clear lines between things and events, and hence we cannot separate 'the Way'as *what* from a way as *how*.

In classical Western metaphysics, the equivocation between one as 'unity' and one as 'uniqueness' tends to be resolved in favour of 'unity'. Thus, in any of the various conceptions of a single-ordered universe assumed by the early systematic philosophers, the many phenomena comprising the world are defined in accordance with unifying first principles which determine the essential reality of the things of the world (see Cosmology). *Dao* is often taken to be this familiar search for the One behind the many.

In classical Chinese reflections on world order, however, the equivocation between one as 'unity' and as 'uniqueness' is usually resolved in favour of the unique. The natural cosmology of classical China does not require a single-ordered cosmos, but invokes an understanding of a 'world' constituted by 'the ten thousand things' (see Chinese philosophy §1). There is no Being behind the beings - only beings are. And *in toto*, these beings are *dao*. Continuity makes *dao* one; difference makes *dao* myriad; change makes *dao* processional and provisional. *Dao* is thus both the One and the many, or better, the field and foci through which it is entertained.

The Chinese 'world as such' is constituted by 'worlding' (*ziran*), a process of spontaneous arising, or literally,

uncaused ‘self-so-ing’, which references no external principle or agency to account for it. The one and the many stand in a holographic relationship: there is the indiscriminate field (*dao*) and its particular focus (*de*). *Dao* as field is always entertained and focused from some perspective or another, from some particular *de* (see De). Just as in a holographic display where each detail contains the whole in an adumbrated form, so each item of the totality focuses the totality as its particular field.

Daodejing

The Daodejing (or Tao Te Ching) is a brief work probably composed during the period 350-250 BC. It later became the most authoritative 'scripture' in the Daoist religious and philosophical tradition, and in modern times has become among the most often-translated and popular works in world religious literature. It recommends cultivating mental calm, an intuitive, non-conceptual understanding of the world, an integrated and balanced personality, a self-effacing manner and a low-key and non-intrusive leadership style. One who has this spirit has dao *(*tao*), which is also conceived of as a cosmic reality, the origin of the world.*

1 Origin and composition

We have no reliable direct information about the origins of the *Daodejing* (the title means 'Classic of *Dao* and *De*'). Its traditional attribution to the legendary and later deified sage Laozi (Lao Tzu) is now widely questioned (see Chan (1963); Graham (1990)). It is traditionally divided into eighty-one very brief numbered 'chapters', each probably consisting of several oral sayings originally coined in a close-knit community, with unifying editorial additions. The term 'Laoist' is used here to refer to the thought of this book so as to differentiate it from other contemporary and later forms of Daoism (see Daoist Philosophy).

2 Concrete advice

The *Daodejing* repeatedly criticizes egotistic self-assertion and boastful self-promotion, and competing with others for social status. It also criticizes 'working' at impressing others by external refinements such as polished speech and cultivated manners; this is the basis for its criticism of contemporary Confucian self-cultivation. Many paradoxical sayings praise ways of being at the opposite extreme: self-effacing public service, appearing 'empty', 'compromised' or 'dull and stupid', and cultivating softness, 'weakness' and femininity (in contrast to the masculine strength much admired by contemporaries).

The *Daodejing* warns against the mental disturbance caused by external stimulation and the attraction of 'desirable' things. It advocates finding contentment in oneself (*Daodejing* 44, 46) and cultivating mental stillness (16, 52). This will give one an inexhaustible source of energy, ensuring good health and enabling one to 'last long', possibly gaining immortality (33).

The *Daodejing* criticizes confidence in the ability of conceptual ('naming') knowledge to grasp reality, probably a criticism of Mohist logicians and the Confucian programme of 'rectifying names' (see Logic in China). It emphasizes the unpredictability of the world as well as the impossibility of capturing true norms in exact verbal formulas. One must rely instead on the intuitive understandings of a properly cultivated mind. The ultimate basis for norms (*dao*) is 'nameless' and can only be conveyed by 'wordless teaching' (*Daodejing* 2, 43).

Much of the *Daodejing* consists of advice about how to rule, probably reflecting its origins in a group of *shi*, men aspiring to administrative or advisory positions in government (Hsu 1965). It criticizes contemporary rulers who exploit peasant society for their own advantage (53, 72, 75), or who rely on physical violence (war-making and capital punishment) to achieve their ends (30, 31, 69, 74). It also strongly criticizes ruling styles that are in any way overbearing or intrusive. A ruler should not strive to be 'awesome' (72), even by trying to set a high moral example for the people (this is probably an anti-Confucian polemic). Again many paradoxical sayings advocate the extreme opposite of these normal tendencies of rulers. Rather than lording it over his subjects, he should attract their allegiance and cooperation by his deferential attitude, treating them as though he is someone 'lower' than they (61, 66, 68). Rather than searching for ego-gratification by high-profile achievements, the best kind of ruler strives to go unnoticed, giving the people the impression that social order is happening 'naturally' (17). A ruler should not try to mould the society according to his own values and ideas; this is 'working on' society, in contrast to which Laoists advise 'not working' (*wuwei*), 'taking the mind of the people as his mind' (49), and fostering and maintaining the organic social harmony already present in the communities he governs ('helping along [their] naturalness' (64)). Rather than being strict, the ruler should have the 'dull and incompetent' appearance (58) of one with a 'muddled mind' (49). When he has to intrude, he should be as non-confrontational as possible, defeating opposition by 'soft' indirect means, or by nipping bad tendencies in the bud (36, 64).

The *Daodejing* expresses opposition to several contemporary 'progressive' movements, such as the encouragement

of personal ambition or rational-utilitarian thought among the peasantry, as a means of increasing material production and political strength. This causes discontent and contention and upsets social harmony, making it difficult for rulers to maintain a healthy (that is, simple traditional agrarian) social order.

3 Deeper dimensions

Many passages in the *Daodejing* speak about a deeper dimension of reality, most notably those that picture *dao* as the origin of the world; the *Daodejing* and the *Zhuangzi* are largely responsible for giving dao the pregnant meaning it came to have in later Chinese tradition (see Dao; Zhuangzi). However, these passages present a set of overlapping images rather than a system of doctrines, and there is no very explicit indication as to how they relate to each other or to the concrete advice outlined above. Consequently, interpretations of this facet of the *Daodejing*'s thought vary widely, and at present nothing can be regarded as settled.

Philosophically inclined modern interpreters have tended to construe this area of Laoist thought on the model of Western 'metaphysics'. On this view, teachings about *dao* constitute an objective transcendent foundation of the worldview taught by the *Daodejing* as a whole. The implicit model here is very often (Fung 1937; Kaltenmark 1969; Schwartz 1985) speculative mysticism, as found in Neoplatonism or Vedānta (see Neoplatonism; Vedānta), or German Idealism (see German Idealism) as found in Hegel and Heidegger: *dao* is an unmanifest Absolute Being underlying but pervading the phenomenal world of beings. Its 'namelessness' refers to the fact that it is beyond all finite determinations that characterize the world of appearances. One then has to posit also a 'manifest' aspect of *dao* which has some positive and definite content, in order to ground the obvious bias of the *Daodejing* towards one side of the various polarities it poses (softness versus hardness, femininity versus masculinity and so on). There are also, however, several anti-mystical philosophical interpreters who construe *dao* in a more naturalist way as something immanent in the world, or as something like 'natural law' (Needham 1962). Finally, Hansen (1992) thinks the *Daodejing* argues a primarily negative and sceptical thesis, that no socially conditioned value judgments have any objective grounding.

However, it can also be argued that self-cultivation rather than speculative philosophy or mysticism is the background for the thought of the *Daodejing* (Roth 1991), and that its teachings about *dao* are to be construed imaginally rather than as philosophical metaphysics (Girardot 1974). On this view (argued in LaFargue 1994), the *Daodejing* imagines a primordial level of human conscious being that is inactive, unaroused, undifferentiated (*pu* (uncarved), *Daodejing* 15, 28, 32, 19), and not involved in conceptual thought ('nameless' and *tong* (merged), 1, 56). Society in general does not value this, but gravitates instead towards more active, 'excited' states, towards the specialized development of prized and admired 'virtues', towards grasping reality by means of refined conceptual (learned) thought, and towards striving to make one's mark on the world. Each of these disturbs the state of organic harmony, both internal and social, that Laoists regard as 'natural'. Laoists want to reverse this conventional value-orientation, insisting that the inactive, undifferentiated, organically harmonious state is the more valuable, and indeed the source of all that is most valuable in life. Expressed in chronological imagery, this is the 'prior' or 'root' state; people ought to reverse their normal tendencies and 'turn back' to cultivating this level of their being (Chapter 10 contains meditation instruction connected with this self-cultivation practice). The idea is not to remain literally inactive, but to 'dwell in' this layer of one's being and let it express itself in the manner of one's active involvement in the world. This will be a manner different from those whose value-orientation is more conventional: it will make one appear feminine rather than masculine, soft and weak rather than hard and strong, and 'empty' (that is, without a strongly felt, sharply defined presence) rather than solid.

One who cultivates this level of being experiences more mental clarity and also has a different perspective, dominated by a distinctive value-orientation. The world appears different to such a person than it does to conventional society. (This is the view of the world expressed in the more practical aphorisms of the *Daodejing*.) Laoists are aware that the character of this changed world has its origin in the state of mind they cultivate. They imagine this state to be a deeper layer of the world itself, expressed by saying it is 'the world's origin'.

On this view, *dao* was for Laoists primarily an internal spirit to be cultivated, imagined as an independent cosmic force or entity informing an ideal state of mind and expressing itself in certain ideal patterns of conduct. This 'subjective' reality of *dao*-as-experienced served as a basis for the vision of a world with *dao* as its source. The *Daodejing* had not yet transformed this into an objectified doctrine about the world that (as in the metaphysical interpretation) a person could adopt intellectually and 'believe in', even in the absence of self-cultivation and the

concrete experience of *dao* (although such an objectifying transformation did happen rather soon after, and can be seen already in the earliest commentaries of Han Feizi and Wang Bi.)

Laoist 'mysticism' was not speculative - mystical insights did not serve as the basis for a set of doctrines about reality - nor was it unitive - Laoists did not strive for union with *dao* for its own sake. Rather, it was developed in practical directions. Dao was valued as a constantly dependable and nourishing internal 'mother' (*Daodejing* 20), sustaining those whose values deprived them of external social support. It also had a strongly political dimension: *dao* as the highest reality gave whoever possessed it the spiritual status of 'pattern/norm for the world', taking over this religious role which previous tradition had assigned to the Zhou Emperor. When such a person attained an administrative or advisory position in government, the *dao* he possessed would ideally inform the policies he promoted, and above all his leadership style (32, 37). Thus, as *dao* radiated from his person as *de*, subtle 'charisma', it would set the tone for the entire society and become the foundation for an ideal social order. This union of 'spiritual' and political interests is a distinctive feature of the *Daodejing*, at least in its final recension; some scholars argue that early Laoist thought was apolitical, and that applying Laoist ideas to problems of governing represents a later stage of development.

Daoist philosophy

*Early Daoist philosophy has had an incalculable influence on the development of Chinese philosophy and culture. Philosophical Daoism is often called 'Lao-Zhuang' philosophy, referring directly to the two central and most influential texts, the Daodejing (or Laozi) and the Zhuangzi, both of which were composite, probably compiled in the fourth and third centuries BC. Beyond these two texts we might include the syncretic Huainanzi (*circa *140 BC) and the Liezi, reconstituted around the fourth century AD, as part of the traditional Daoist corpus.*

Second in influence only to the Confucian school, the classical Daoist philosophers in many ways have been construed as both a critique on and a complement to the more conservative, regulatory precepts of their Confucian rivals. Daoism has frequently and unfortunately been characterized in terms of passivity, femininity, quietism and spirituality, a doctrine embraced by artists, recluses and religious mystics. Confucianism, by contrast, has been cast in the language of moral precepts, virtues, imperial edicts and regulative methods, a doctrine embodied in and administered by the state official. The injudicious application of this yin-yang-*like concept to Daoism and Confucianism tends to impoverish our appreciation of the richness and complexity of these two traditions. Used in a heavy-handed way, it obfuscates the fundamental wholeness of both the Confucian and Daoist visions of meaningful human existence by imposing an unwarranted conservatism on classical Confucianism, and an unjustified radicalism on Daoism.*

There is a common ground shared by the teachings of classical Confucianism and Daoism in the advocacy of self-cultivation. In general terms, both traditions treat life as an art rather than a science. Both express a 'this-wordly' concern for the concrete details of immediate existence rather than exercising their minds in the service of grand abstractions and ideals. Both acknowledge the uniqueness, importance and primacy of the particular person and the person's contribution to the world, while at the same time stressing the ecological interrelatedness and interdependence of this person with their context.

However, there are also important differences. For the Daoists, the Confucian penchant for reading the 'constant dao*' myopically as the 'human* dao*' is to experience the world at a level that generates a dichotomy between the human and natural worlds. The argument against the Confucian seems to be that the Confucians do not take the ecological sensitivity far enough, defining self-cultivation in purely human terms. It is the focused concern for the overcoming of discreteness by a spiritual extension and integration in the human world that gives classical Confucianism its sociopolitical and practical orientation. But from the Daoist perspective, 'overcoming discreteness' is not simply the redefinition of the limits of one's concerns and responsibilities within the confines of the human sphere. The Daoists reject the notion that human experience occurs in a vacuum, and that the whole process of existence can be reduced to human values and purposes.*

*To the extent that Daoism is prescriptive, it is so not by articulating rules to follow or asserting the existence of some underlying moral principle, but by describing the conduct of an achieved human being - the sage (*shengren*) or the Authentic Person (*zhenren*) - as a recommended object of emulation. The model for this human ideal, in turn, is the orderly, elegant and harmonious processes of nature. Throughout the philosophical Daoist corpus, there is a 'grand' analogy established in the shared vocabulary used to describe the conduct of the achieved human being on the one hand, and the harmony achieved in the mutual accomodations of natural phenomena on the other.*

The perceived order is an achievement, not a given. Because dao *is an emergent, 'bottom-up' order rather than something imposed, the question is: what is the optimal relationship between* de *and* dao*, between a particular and its environing conditions? The Daoist response is the self-dispositioning of particulars into relationships which allow the fullest degree of self-disclosure and development. In the Daoist literature, this kind of optimally appropriate action is often described as* wuwei*, 'not acting wilfully', 'acting naturally' or 'non-*assertive *activity'.* Wuwei*, then, is the negation of that kind of 'making' or 'doing' which requires that a particular sacrifice its own integrity in acting on behalf of something 'other', a negation of that kind of engagement that makes something false to itself.* Wuwei *activity 'characterizes' - that is, produces the character or ethos of - an aesthetically contrived composition. There is no ideal, no closed perfectedness. Ongoing creative achievement itself provides novel possibilities for a richer creativity.* Wuwei *activity is thus fundamentally qualitative: an aesthetic category and, only derivatively, an ethical one.* Wuwei *can be evaluated on aesthetic grounds, allowing that some*

relationships are more productively wuwei *than others. Some relationships are more successful than others in maximizing the creative possibilities of oneself in* one's *environments.*

This classical Daoist aesthetic, while articulated in these early texts with inimitable flavour and imagination, was, like most philosophical anarchisms, too intangible and impractical to ever be a serious contender as a formal structure for social and political order. In the early years of the Han dynasty (206 BC*-*AD *220), there was an attempt in the Huainanzi to encourage the Daoist sense of* ethos *by tempering the lofty ideals with a functional practicality. It appropriates a syncretic political framework as a compromise for promoting a kind of practicable Daoism - an anarchism within expedient bounds. While historically the Huainanzi fell on deaf ears, it helped to set a pattern for the Daoist contribution to Chinese culture across the sweep of history. Over and over again, in the currency of anecdote and metaphor, identifiably Daoist sensibilities would be expressed through a range of theoretical structures and social grammars, from military strategies, to the dialectical progress of distinctively Chinese schools of Buddhism, to the constantly changing face of poetics and art. It can certainly be argued that the richest models of Confucianism, represented as the convergence of Daoism, Buddhism and Confucianism itself, were an attempt to integrate Confucian concerns with human community with the broader Daoist commitment to an ecologically sensitive humanity.*

1 Classical Daoism

Before attempting to characterize the lineaments of Daoist philosophy, a brief discussion of the meaning of the term 'classical Daoism' is necessary. Unlike Confucianism, the 'school' of Daoism, *daojia*, does not name a tradition constituted by a founding thinker. Indeed, the term 'Daoism' is itself an *ex post facto* creation of subsequent editors and historians.

Daoism is first named as a school by Sima Tan in the *Shiji (Records of the Historian)* in the second century BC; and because Sima Tan's concern was classifying schools in terms of their contributions to 'the art of rulership', there was no expressed connection at this time between Zhuangzi and Laozi, later recognized as the two principal Daoist thinkers. In Sima Tan's classification, the Daoists are listed as one of six schools of thought, the others being the Yin-Yang school (see Yin-yang), the Confucians (see Confucian philosophy, Chinese), the Mohists (see Mohist philosophy), the Legalists (see Legalist philosophy, Chinese) and the School of Names (see Logic in China).

In the first century AD, Ban Gu in the *Hanshu (History of the Former Han Dynasty)* included the writings of Zhuangzi and Laozi together under the heading of 'Daoism' as one of nine philosophical schools. By the first quarter of the fourth century, the principal texts of Daoism were recognized as the *Daodejing* (also called the *Laozi*) and the *Zhuangzi* (see Daodejing; Zhuangzi), along with the respective commentaries by Wang Bi (AD 226-49) and Guo Xiang (d. early fourth century), texts such as the *Guanzi* and *Heguanzi* and writings attributed to the Yellow Emperor (Huangdi). In 1973, an early Han tomb was excavated at Mawangdui and two silk copies of the *Daodejing* were discovered, along with four texts originally attributed to the Yellow Emperor that have a distinctly Legalist flavor. The bundling of these texts together suggests an attempt to borrow the authority of Emperor Huangdi, the legendary founder of the Chinese state, for a Legalist interpretation of Laozi's doctrines. There is some scholarly opinion that it was this Legalistic Daoism, called Huang-Lao, rather than Lao-Zhuang Daoism which actually defined the school during the Han dynasty.

A further complication in explaining the sense of 'Daoism' results from the fact that 'the School of the Way', *daojia*, is to be distinguished from *daojiao*, what may be termed the 'the Doctrine of the Way', with the latter traditionally dating from the middle of the second century. *Daojiao* is the foundation of the organized Daoist religion which has persisted down to the present day. On the surface at least, many of the rituals and doctrines of this religious Daoism do not seem to cohere with the spirit of the more philosophical form of Daoism. Until recently scholars of Daoism, particularly those in the West, have typically drawn a rather sharp distinction between the *daojia* and *daojiao*. More recently, with the translations of Daoist 'religious' texts of the medieval period, there have been attempts to identify a 'mystical philosophy' in the *daojiao* which has its roots in the thought of Laozi and Zhuangzi. It should also be said that many of the contemporary practitioners of so-called religious Daoism distinguish themselves from the philosophical Daoists in terms of the esoteric or 'inner' teachings and practices constituting the central identity of their community versus the exoteric or 'outer' teachings of the *daojia*. Having acknowledged this distinction, there is some contemporary scholarly concern regarding the tendency to over-intellectualize the philosophical tradition at the expense of a meditative and hygenic regimen that

seems implicit in these texts.

Perhaps it is fitting that the historical roots of what has come to be identified as Daoist thinking should be obscure. In fact, relatively fluid identity of the Daoist tradition has in part been responsible for its widespread influence beyond the borders of China. Both the *Daodejing* and the writings of Zhuangzi have become classics of world philosophical and spiritual literature, taking their place as expressions of that *philosophia perennis* which touches the deepest layers of human sensibility. Certainly the hundreds of translations of the *Daodejing* attest to this status.

The usual distinction made between the classical forms of Confucianism and Daoism is in terms of the most general context with which each is concerned. Confucians focus upon issues relevant to a ritualized human society (see Confucian philosophy, Chinese; Confucius), while Daoists concern themselves with the natural ambiance. Such a distinction has but qualified merit, however, since it really characterizes only the overall emphasis of the contrasting models of thinking. The familial or bureaucratic metaphor employed by the broad Confucian tradition is most relevant to the concerns of social structure and harmony, though Han speculations led to the extension of this metaphor to the broadest of cosmological issues. In a similar manner, the more naturalistically inclined Daoists begin with the ‘Six Realms’ - heaven, earth and the four directions - but are quite capable of bringing the model of accommodation, developed with reference to the ten thousand things, to bear upon concrete social and political concerns in a variety of both constructive and critical manners. Indeed, the *Daodejing* is generally considered to be a political manual dealing with the proper guidance of society.

Thus the distinction between Daoism and Confucianism, at what we in the West would term the ‘philosophical’ level, is perhaps not as great as the majority of commentators have claimed. In fact, were we to search for something like a central insight or commitment giving rise to the most general speculations associated with the two visions, we might find that there is a ‘single thread’ running through both Confucianism and Daoism. The central focus of both Confucian and Daoist forms of thinking is the form of engagement which might be termed ‘deference’. In Confucianism one may discuss this deferential activity in terms of the notion of *shu*, a sort of analogical activity which encourages one to put oneself in another’s place as a strategy for determining appropriate conduct. This activity is broadly shaped by a system of rituals (*li*) which characterize the structures of society and the roles through which various human activities are expressed (see Law and ritual in Chinese philosophy).

In Daoism, deference involves a yielding (and being yielded to) grounded in a recognition of the uniqueness of that to which deference is paid. One may best express the meanings of deferential activity in Daoism through the notions of *dao*, *de* and the so-called *wu*-forms: *wuwei*, *wuzhi* and *wuyu*.

2 Fundamental notions: *dao*

> *Dao* engenders one,
> One engenders two,
> Two engenders three,
> And three engenders the myriad things.
> The myriad things shoulder *yin* and embrace *yang*,
> And mix the *qi* to achieve harmony.

(*Daodejing* 42)

Dao is the process of the world itself, the ‘way’ of things. In Daoism, the relevant contrast is not between the cosmological ‘whatness’ of things and the ontological ‘thatness’ of things, but rather between the world as ‘chaos’ (*hundun*) - the sum of all orders - and any given world as construed from some particular perspective (*de*), that is, in terms of any particular one of the orders (see Dao).

Dao is not organic in the sense that a single pattern or *telos* could be said to characterize its processes. It is not *a* whole, but many such wholes. It is not a One to which the Many reduce. Its order is not rational or logical, but aesthetic; there is no transcendent pattern determining the existence or efficacy of the order. The order is a consequence of the particulars comprising the totality of existing things. This interpretation of *dao* makes of it a totality not in the sense of a single-ordered cosmos, but rather as the sum of all potential orders. Any given order is an existing world that is construed from the perspective of a particular element within the totality; but, as a single

world, it is a selective abstraction from the totality of possible orders. Such a limited order cannot serve as fundament or ground. In the Daoist sensibility, all differences are cosmological differences, that is, differences among particular components which, at some moment, comprise the order.

The Daoist understanding of the world is not as an ordered whole but as ‘the ten thousand things’ (*wanwu*). As this term indicates, there is in effect no concept of ‘cosmos’ at all, insofar as that notion could be said to entail a coherent, single-ordered world which is any sense enclosed or defined. The Daoists are therefore primarily ‘acosmological’ thinkers. In the absence of some overarching *archē* or ‘beginning’ as an explanation of the creative process, and under conditions which are thus ‘anarchic’ in the philosophic sense of this term, although nature might indeed be conventionally classified in terms of ‘kinds’, such categories would by no means be natural kinds. Difference is always prior to similarities.

The Chinese binomial most frequently translated as ‘cosmos’ is *yuzhou*, a term that overtly expresses the interdependence between time and space. For the Daoists - indeed for the classical Chinese generally - time pervades everything and is not to be denied; it is not derivative of matter, but a fundamental aspect of it. Unlike traditions which devalue time and change in pursuit of the timeless and eternal, in classical China things are always processional and transforming (*wuhua*) and hence are always provisional. In fact, in the absence of some claim to objectivity that ‘objectifies’ and thus makes ‘objects’ of phenomena, the Chinese tradition does not have the separation between time and entities that would allow for either time without entities or entities without time: there is no possibility of either an empty temporal corridor or an eternal anything (in the sense of being timeless).

What encourages us within a Western metaphysical tradition to separate time and space is our inclination inherited from the Greeks to see things in the world as fixed in their formal aspect, and thus as bounded and limited (see Time §1). But if, instead of giving ontological privilege to the formal aspect of phenomena, we observe them in light of their ceaseless transformation, we are able to temporalize them and perceive them as ‘events’ rather than ‘things’, where each phenomenon is some current or impulse within a temporal flow. In fact, the pervasive capacity of the world to transform continuously is the meaning of time itself. It is because things in the world are reproductive that time is reproductive. Since the world is always entertained from one perspective or another, and since the temporal aspect is never abstract, fictive or replicated, any perspective is an advancing path that is neither linear nor cyclical, but both. Time-space-matter is an advancing spiral. The expression ‘advancing path’ is particularly appropriate, because it is this image of our passage in the world that is captured in *dao* as a grounding metaphor pervasive in the tradition (see Processes).

The most provocative characterization of *dao* in the *Daodejing* is as both ‘nameless’ and ‘nameable’:

> *Dao* can be spoken of, but that is not constant *dao*;
> The name can be named, but that is not the constant name;
> The nameless is the beginning of the heavens and the earth;
> The named is the mother of the myriad things.
> Dwell constantly in nothing in order to observe its mysteries;
> Dwell constantly in something in order to observe its boundaries.

(*Daodejing* 1)

If *dao per se* is the ‘way’ of things, construed as all of the processes of becoming, then nameless and nameable *dao* characterize the functions of ‘not-being present’ and ‘being present’ respectively, as abstracted from the process of becoming-itself. *Dao* is the *that which*: that which *is* and that which *is not* are the polar elements of ‘becoming-itself’.

3 Fundamental notions: *de*

It would be easy to misunderstand this interpretation as claiming a far greater coherence for the Daoist vision than is likely. One must look carefully at the meanings of the explanatory categories *you* and *wu*, conventionally translated as ‘being’ and ‘not-being’, in the Chinese tradition (see You-wu). For example, *wu* means ‘have not’ or ‘there is not’, which readily contrasts with the sense of not-being as ‘nothing’ or ‘no entity’. The sense of *wu* is of the absence of specific concrete things. The correlative sense of *you* in this context is the presence of these same concrete things.

If one looks at Daoism with the appropriately adjusted senses of 'being' and 'not-being', the notion of *dao* as the 'that which' loses its ontological tone. There is only 'this' and 'that'. To translate this idea as 'only beings are' is quite appropriate provided one does not look for any Being standing behind or beneath or beyond these beings, and provided one does not interpret 'are' in an existential sense. The best manner of avoiding such a confusion is simply to say, since there are only 'thises' and 'thats', the locution 'only beings are' is more aptly expressed as 'beings only' or 'these beings'.

Beings are 'thises' and 'thats'. *Dao*, construed as 'that which is' and 'that which is not' - nameable and nameless *dao* - characterizes the process of existence and experience as 'becoming-itself'. This reflexive notion, however, does not name an 'itself' which becomes; rather, the locution 'becoming-itself' refers simply to the unsummed processes of becoming *per se*. It is these processes that are entailed by the notion of *dao*.

What this means, of course, is that Daoism expresses a radical acosmology. If we wish to understand the sense in which 'difference' is to be understood relative to the parity of things, we must restrict ourselves solely to the question of the differences among particular things. Each particular element in the totality has its own *de*. *De* is best understood as a particular focus that orients an item in a field of significances such that it achieves its own intrinsic excellence (see De). The *de* of an element provides the perspective from which it construes all other items in its environs. In this manner each item with respect to its *de* 'names' and creates a world. *Dao* and *de* are related as field and focus respectively. The relations of *dao* and *de* are 'holographic': that is, each element in the totality of things contains the totality in an adumbrated form. The particular focus of an item establishes its world, its environment; the totality as a noncoherent sum of all possible orders is adumbrated by each item.

The *Zhuangzi* contains a passage in which this notion of 'locus' or 'place' is presented as being integral to what it means to know:

> Zhuangzi and Huizi were strolling across the bridge over the Hao river. Zhuangzi observed, 'The minnows swim out and about as they please - this is the way they enjoy themselves.'
>
> Huizi replied, 'You are not a fish - how do you know what they enjoy?'
>
> Zhuangzi returned, 'You are not me - how do you know that I don't know what is enjoyable for the fish?'
>
> Huizi said, 'I am not you, so I certainly don't know what you know; but it follows that, since you are certainly not the fish, you don't know what is enjoyment for the fish either.'
>
> Zhuangzi said, 'Let's get back to your basic question. When you asked '*From where* do you know what the fish enjoy?' you already knew that I know what the fish enjoy, or you wouldn't have asked me. I know it from here above the Hao river.'

(*Zhuangzi* 17)

Zhuangzi is not just depending upon linguistic ambiguity in order to win an argument. He has a more philosophic point to make: he wants to deny the objectivity of knowledge in the sense of the independence of the world as known, from the knower. For Zhuangzi, knowledge is performative and a function of fruitful correlations. It is a 'realizing' of a world in the sense of 'making it real', and the knower and the known are inseparable aspects of this same event. Agency cannot be isolated from action. One and one's posture or perspective is thus integral to what is known; where you are and how you know are mutually entailing. Knowledge is proximity. Zhuangzi's experience with the fish makes his world continuous with the world of the fish, and as such, his claim to knowledge is a claim to having been there. Being continuous with the fish and collaborating with them in the experience does not deny the fish their difference. In fact, it is only through Zhuangzi's deference to their difference - allowing them to be what they are - that the experience can be optimally fruitful and he can really come to know these particular fish (see Knowledge, concept of).

The Daoist belief in the 'the parity of things' celebrates the *differences* that exist among the items of the totality. The manner in which all things are *similar* is easily stated: although the *de* of things, being ever unique, are hierarchical in their relations one to the other, at the same time they have parity in the sense that each *de* is necessary for every other *de* to be what it is. With no Being behind the beings of the world, the way of things is both continuous and radically perspectival. There can be no standards such as the 'great chain of being' or the

'ladder of perfection' establishing ontological hierarchies (see Being §§1-2). What we have instead is both the uniqueness of each perspective, and parity among them.

4 Person and world: the *wu*-forms

Having indicated the sense of parity affirmed by the Daoists, and the deferential activity such an understanding entails, we may now attempt to grasp in greater detail how the Daoists seek to respond to their natural and social environs. As noted earlier, in Confucianism, deference (*shu*) operates within ritual patterns (*li*) shaped in accordance with the familial relationships extending outward into society and culture (see Confucian philosophy, Chinese). By contrast, Daoism expresses its deferential activity through what we shall call the *wu*-forms, *wuzhi*, *wuwei* and *wuyu*: that is, 'no-knowledge', a sort of knowing without resort to rules or principles; 'no-action', or actions in accordance with the *de* (particular perspective) of things, and 'no-desire', or desiring which does not seek to own or control its 'object' (which in effect makes it an 'objectless desire'). In each of these cases, it is necessary to remain sensitive and responsive to the particular perspective (*de*) of what is to be known, what is to be acted in accordance with, or what is to be desired.

Since the *wu*-forms bear some skewed resemblance to the faculties of the tripartite *psychē* which has played such an important role in Western speculations since Plato, we shall begin by noting the contrasting problematics underlying the distinctive interpretations of knowledge, action and desire in classical Daoism and dominant strains of the Western tradition. The Platonic *psychē*, and its permutations throughout the subsequent history of Western thought, has provided us with a wealth of interpretations of the modalities of knowing, acting and desiring which comprise the structure of the self (see Psychē). The heritage of the self construed as a tripartite structure is one of conflict, the soul at war with itself. In Plato, the primary conflict of course is between knowledge and ignorance, reflected in such mottos as 'To know the Truth is to do the truth' and 'You shall know the Truth and the Truth shall make you free'. Allied with this conflict, internal to reason itself, is that tension between the appetitive and the spirited elements on the one hand, and the rational elements on the other. This is essentially a conflict between mind and body, ramified with the confluence of Hebraic and Hellenic sensibilities. It is well expressed in the words of St Paul: 'The good that I would do, I do not do; the evil that I would not do, that I do', and receives perhaps its profoundest expression in Augustine's *Confessiones* in the form of a war between passions and the will, one demanding the satisfactions of desire, the other seeking obedience to the will of God (see Augustine). The conflict is again succinctly stated in a familiar doctrine of David Hume: 'Reason is and always shall be, a slave to the passions' (see Dualism; Emotions, philosophy of; Human nature).

These permutations of the soul at war are so deeply embedded in our own intellectual culture as to shape unconsciously much of our analysis of alternative psychological and cultural sensibilities. It is essential, therefore, to recognize that the model of the tripartite self has little relevance to the dynamics of Chinese models of the person, and the relation of those models to their larger social and cultural context. A signal of this fact is that there is no fundamental mind-body dualism with which to contend; and since this dualism sets up the principal conflict within the self between reason on the one hand and the affective and volitional components on the other, any conflict in the Daoist understanding of person obviously cannot be between heart and mind, or mind and will. In fact, the goal of cultivation of the self for the Daoist is predicated upon a different dynamic altogether: the attempt to move from activities of knowing, feeling and action shaped by construal to those shaped by deference (see Self-cultivation, Chinese theories of).

Having said all this, there are terms such as *zhi*, *wei* and *yu* which initially seem to correlate rather closely with what we in the Western tradition call knowing, acting and desiring. If the Daoist self is not divided in the manner of the Western model of the tripartite soul, how are we to account for these three modalities? The *wu*-forms must be thought of as activities that establish the deferential relations which constitute the self at any given moment.

5 Person and world: the *wu*-forms (cont.)

Wuzhi, as 'no-knowledge', means the absence of a certain kind of knowledge, specifically the sort dependent upon ontological presence (see Zhi). Knowledge grounded in a denial of ontological presence does not presuppose a single-ordered world and its intellectual accoutrements. It is therefore 'unprincipled knowing', the sort of knowing that does not appeal to rules or principles determining the existence, meaning or activity of a phenomenon. *Wuzhi* provides one with a sense of the *de* of a thing, its particular focus, rather than yielding some understanding of that

thing in relation to some concept or natural kind or universal. Ultimately, *wuzhi* is expressed as a grasp of the *daode* relationship of each encountered item, which permits an understanding of the totality construed from the particular focus (*de*) of that item.

Wuzhi, or 'knowing without principles', is tacit and, though inexpressible in literal terms, may be communicated though parabolic and imagistic language. A Confucian critic challenged the Daoist claim which begins the *Daodejing* - '*Dao* can be spoken of, but it is not constant *dao*' - by asking: 'If constant *dao* cannot be spoken of, how is it that the author of the *Daodejing* used several thousand characters in speaking of it?' The Daoist replied: 'I make for you a beautiful embroidery of drakes and pass it along to you for your admiration. I cannot, however, show you the golden needle by which it was made.' Such parabolic language does not presuppose a literal ground. Parabolic language, therefore, is constitutive of discourse itself. Language is, from the beginning, a language of difference and particularity. It is this language that permits the communication of the results of *wuzhi*.

Knowledge, as unprincipled knowing, is the entertainment of the world on its own terms without recourse to rules of discrimination which separate one sort of thing from another sort. The *Huainanzi*, a Han dynasty eclectic text with a strong Daoist colouration (see Huainanzi), reports on this kind of mirror-like 'knowing':

> Therefore, the sage is like a mirror -
> He neither sees things off nor goes out to meet them,
> He responds to everything without storing anything up.
> Thus, he is never injured through the myriad transformations he undergoes…
> It is because the mirror and water do not install cleverness beforehand that when they come into contact with shapes that are square, round, bent and straight, they are unable to escape being shown for what they are.
>
> (*Huainanzi* 6 and 1)

Rules of thumb, habits of action, customs, fixed standards, methods, stipulated concepts, categories, commandments, principles, laws of nature: all these require us to 'welcome things as they come and escort them as they go'. Having stored past experience and organized it in terms of fixed standards or principles, we anticipate, celebrate and recall a world patterned by these discriminations. The sage, however, mirrors the world and 'neither sees things off nor goes out to meet them'. As such, he 'responds to everything without storing anything up'. This means that he mirrors the world *at the moment* in a way that is undetermined by the shape of a world passed away, or by anticipations of a world yet to come.

6 Person and world: the *wu*-forms (cont.)

Wuwei, often misleadingly translated as 'no action' or 'non-action', involves the absence of a specific sort of action, namely, coercive action which interferes with the particular focus (*de*) of those things within one's field of influence. Actions untainted by stored knowledge or ingrained habits are unmediated, unstructured, unprincipled and spontaneous. As such, they are consequences of deferential responses to the item or event in accordance with which, or in relation to which, one is acting. These actions are *ziran*: 'spontaneous' and 'self-so-ing'. They are *nonassertive* actions.

The 'grand analogy' in the *Daodejing* is that *dao* is to world as ruler is to people. *Dao*, as the discernible rhythm and regularity in the world around us, is non-impositional: '*Dao* is constantly non-assertive (*wuwei*) yet there is nothing which is not done' (*Daodejing* 37).

In the Chinese exercise form known as *taijiquan*, there is a practice known as 'push-hands' (*duishou*) which well-illustrates *wuwei*. Two individuals facing one another perform various circular movements of the arms while maintaining minimal hand contact. The movement of each individual mirrors that of the other. *Wuwei* is realized when the movements of each are sensed, by both parties, to be uninitiated and effortless - that is, *spontaneous*. Presumably, one can employ such mirroring responses in 'the art of rulership', providing a sort of nonconstruing model for the guidance of the state. Such is the testimony of the *Daodejing*:

> Thus, the sage says:
> I am nonassertive (*wuwei*)
> And the people transform themselves;

I cherish stillness,
And the people attune themselves;
I do not intervene,
And the people are prosperous of their own accord;
I am objectless in my desires,
And the people retain their natural genuineness of their own accord.

(*Daodejing* 57)

And again:

[The sage] constantly causes the people to seek ‘unprincipled understanding’ and to be objectless in their desires,
And as for the erudite - they wouldn’t dare to do anything.
In simply acting non-assertively,
Everything is properly ordered.

(*Daodejing* 3 (following the Mawangdui text for the last line))

This attitude is carried over into the human world: in government, impositional power is a major concern so the consummate political model in Daoism, corresponding to *dao*, is described as *wuwei* and *ziran*:

The most excellent ruler: the people do not even know that there is a ruler.
The second best: they love and praise him.
The next: they stand in awe of him.
And the worst: they look on him with contempt.
Inadequate integrity in government
Will result in people not trusting those who govern.
So hesitant, the ruler does not speak thoughtlessly.
His job done and the affairs of state in order,
The people all say: ‘We are naturally like this [*ziran*].’

(*Daodejing* 17)

Spontaneous action is a mirroring response. As such, it is action which accommodates the other to whom one is responding on their own terms. Such spontaneity involves recognizing the continuity between oneself and the other, and responding in such a way that one’s own actions, while serving one’s own ends, at the same time promote the interests and well-being of the other. This does not lead to imitation but to complementarity. Handshakes and embraces are actions which both presuppose a recognition of the stance of the other, and complete that stance. When the music starts to play and your partner opens his arms, the dance proceeds as a dyadic harmony of nonassertive actions: provided, of course, you and your partner defer to one another.

7 Person and world: the *wu*-forms (cont.)

Perhaps the best characterization of the term *wuyu* is ‘objectless desire’. Since neither unprincipled knowing nor nonassertive action can in the strict sense objectify a world or any element in it - that is, make discrete and independent objects out of one’s environment - the kind of desiring associated with the Daoist sensibility is in the strictest sense ‘objectless’. The ‘enjoyments’ associated with *wuyu* are possible without the need to define, possess or control the occasion of one’s enjoyment.

Thus, *wuyu*, rather than involving the cessation of desire, represents the achievement of *deferential desire*. Desire, based upon a mirroring understanding (*wuzhi*) and a nonassertive relationship (*wuwei*), thus allowing for the integrity of whatever is entertained, is shaped not by the desire to own, control or consume but simply to celebrate and to enjoy. Desire is for those things desirable in part because they *stand to be desired*. But those things which stand to be desired must themselves be deferential, which means that they cannot *demand* to be desired; for to demand to be desired is to seek a kind of seductive control over the desirer. In a world of events and processes in which discriminations are recognized as conventional and transient, desire is predicated upon the ability at any

given moment to ‘let go’. It is in this sense that wuyu is a nonconstruing, objectless, desire.

The problematic of desire familiar to the Western tradition is expressed by Plato’s definition of Eros as ‘the son of Resource and Need’. Erotic desire is predicated upon a motivation to attain an absent object. Once attained, desire ceases. The resolution of the problem of desire in Plato comes from learning what is truly desirable - namely, knowledge. Complete attainment of knowledge is not possible in this life, so desire continues as an unabated, ultimately harmonizing, motivation to increase one’s understanding, rather than as a movement from one desired object to the next in a frustrated attempt to achieve final satisfaction (see Desire).

The Daoist problematic with respect to desire does not concern what is desired, but rather the manner of the desiring. Objectless desire always allows for letting go. Enjoyment for the Daoist is realized not in spite of the fact that one might lose what is desired, but because of this fact. The world is a complex set of processes of transformation, never at rest. In Plato, the desire for knowledge is the only thing that can define both embodied and disembodied existence; it is the only desire that can be permanent and eternal. In Daoism, transient desire is the only desire that lets things be, that does not construe the world in a certain manner, and that does not seek to apply the brakes on a world of changing things.

The key to understanding *wuyu* - indeed of all these *wu*-forms that are constitutive of the Daoist self - lies in the contrast between ‘objects’ and ‘objectivity’. From a Western perspective, it appears that the thoughts expressed in both the *Zhuangzi* and the *Daodejing* represent something like what would in the West be termed a realism (see Realism and anti-realism). Beyond the confusions introduced by language, and by our own distorted perceptions and tendentious categorizations, there is, with properly Daoist qualifications, an ‘objectively’ real world. Our task is to entertain that world as ‘objectively’ as possible. The problem begins when we believe that the objective world is a world of objects: concrete, unchangeable things which we encounter as over against us, things which announce themselves to us by saying ‘I object!’ For the Daoist, the objective world cannot be objective in this sense. It is a constantly transforming set of events or processes which belie the sorts of discriminations that would permit a final inventory of the furniture of the world:

> Maojiang and Lady Li were beauties for human beings, but fish upon seeing them would seek the deeps, birds on seeing them would fly high, and deer upon seeing them would dash off. Which of these four understands what is really handsome in this world?
>
> (*Zhuangzi* 2)

The moment we begin to discount these other views of Lady Li, we have drained a great deal of significance from the notion of ‘beauty’ by setting up exclusive standards which determine not only the truly beautiful but the unacceptably ugly. Further, these fixed standards - whether of beauty or goodness or justice - are the means of creating a world of fixed objects. Those things or situations which meet the standards are themselves defined and delimited, closed to any other changes than those involved in degradation and decay, that is, failure to realize the demands set by the standard.

Paradoxically, therefore, for the Daoist the objective world is objectless. The sage envisions a world of transforming events which may, for whatever reason, be frozen momentarily into a pattern of discrimination, but which can be recognized, when seen clearly, as beyond such distinctions:

> There is nothing which is not a ‘that’, and nothing which is not a ‘this’. Because we cannot see from a ‘that’ perspective but can only know from our own perspective, it is said that ‘that’ arises out of ‘this’ and ‘this’ further accommodates ‘that’. This is the notion that ‘this’ and ‘that’ are born simultaneously. And even though this is so, being born is simultaneously dying and vice versa; being acceptable is simultaneously being unacceptable and vice versa; accommodating right is accommodating wrong and vice versa. It is for this reason that the sage, illuminating this situation with the way things really are rather than going along with discriminations, is also a case of accommodating what is right and what is ‘this’. But ‘this’ is also ‘that’ and vice versa. And a ‘this’s’ ‘that’ further has one set of right and wrong while ‘this’ has another. In truth, is there really such a thing as ‘this’ and ‘that’ or not?
>
> Where neither ‘this’ nor ‘that’ has an opposite
> Is called the hinge of *dao*,
> And as soon as the hinge is fitted to its bracket

> It can respond endlessly

(*Zhuangzi* 2)

The *wu*-forms - *wuzhi*, *wuwei*, *wuyu* - all provide a way of entertaining and deferring to an object-less world. Thus the sage is concerned with that sort of knowing, acting and desiring which does not depend upon objects. This point is crucial to the Daoist understanding of both self and world. The discriminated, and discriminating, self of the sort recognized in the contemporary West comes into being through encountering a world of things which effectively stand over against and object to him (see Perception). In Daoism, however, personality is forgotten to the extent that discriminated objects no longer constitute the environs of the self.

The consequence of this transformed vision is that knowing, acting and desiring are no longer based upon *construal*. The affirmation of principles as fixed guides for thought and conduct leads us to construe the object of our knowledge by recourse to those principles. An item becomes one of a *kind*, or an instrument for the achievement of an end. Feeling ourselves in tension with objectified others leads us to act in an aggressive or defensive manner to effect our will. Desire motivated by an object leads us to seek possession of that which is desired, allowing it significance only insofar as it meets our need. An individual intoxicated by objects narrows, truncates, and obfuscates the world as it is. Such a person fails to recognize the bottomlessness of each particular phenomenon, leaving off an appreciation of it at the point that the phenomenon ceases to resonate with one's own expectations of it. On the other hand, unprincipled knowing, nonassertive action and objectless desire have this in common: to the extent they are successful, *they leave the world as it is*.

8 The transformation of things: *wuhua*

As we have said, the Daoist self is above all deferential. Deferring to the ways of things as they truly present themselves involves the expression of mirroring responses to environing circumstances. Mirroring such a world in fact involves the mirroring of an indefinite number of worlds since each item is the particular focus of a world. In his commentary on the *Daodejing* 5, Wang Bi notes that 'the myriad things acquire proper order and patterning among themselves'. In ordering themselves, they thereby order a world. Mirroring the individual things in their distinctive particularities therefore involves mirroring a complex set of overlapping orders, each with its own distinctive centre.

Obviously, the construing individual could not but treat such a world as chaotic in the extreme. The deferential self, on the other hand, sees these overlapping orders as a richly spontaneous array of patternings. The famous account of Lord Hundun - Lord Chaos - which closes the Inner Chapters of the *Zhuangzi* is appropriate here:

> The ruler of the North Sea was 'Swift', the ruler of the South Sea was 'Sudden', and the ruler of the Central Sea was 'Chaos'. Swift and Sudden had on several occasions encountered each other in the territory of Chaos, and Chaos had treated them with great hospitality. Swift and Sudden, devising a way to repay Chaos' generosity, said: 'Human beings all have seven orifices through which they see, hear, eat, and breathe. Chaos alone is without them.' They then attempted to bore holes in Chaos, each day boring one hole. On the seventh day, Chaos died.

(*Zhuangzi* 7)

The construing self, relying upon its own seven orifices alone as its strategy for shaping the world, closes down the spontaneity of the unordered totality. But why shouldn't one wish to bring order out of Chaos? A reasonable question indeed, if chaos is the confusion and disarray which Western mythology describes. But if 'chaos' is a noncoherent sum of all orders - perhaps better rendered positively as 'spontaneity' - then imposing order on it means simply selecting one of a myriad candidates for order and privileging that one over the rest.

Obviously something more needs to be said concerning how one might go about actually mirroring the parity of all things. After all, the practical effect of giving each thing its due, when that means allowing it to focus a world from its own peculiar perspective, would seem to be disastrous. We can, however, follow the 'logic' of the Daoist sage at least this far: The most profound experience of the sage is not that of the Oneness *of* all things, or of Oneness *with* all things; it is closer to the experience of the particularity of all things. The experience of unity relevant to the Daoist is of 'this one' and 'that one'. Daoists do not 'become one with all things'; rather, as deferential, they approach becoming one with this or that thing. In effect, the sage becomes one with *all* other things only through

celebrating continuity with other things based upon an intuition of parity.

When the *Zhuangzi* recommends that we become 'one with all things', this is not a Vedānta-like call to surrender one's particularity and dissolve into a unitary and perfect whole. Rather, it is a recognition that each and every unique phenomenon is continuous with every other phenomenon within one's field of experience. Is this an exhaustive claim: are we talking about *all* phenomena? Because the world is processional and because its creativity is *ab initio* rather than *ex nihilo* - a creativity expressed across the careers of its constitutive phenomena - any answer to this question would have to be provisional. Phenomena are never either atomistically discrete nor complete. The *Zhuangzi* recounts:

> With the ancients, understanding had gotten somewhere. Where was that? Its height, its extreme, that to which no more could be added was this: some of them thought that there had never begun to be things. The next lot thought that there are things, but that there had never begun to have boundaries among them. The next lot thought that there are boundaries among things, but that there had never begun to be the acceptable and unacceptable among them…
>
> (*Zhuangzi* 2)

But if the world is not a single, unitary cosmos, with rules and standards and laws finally determining its order - if the world, on the contrary, is the noncoherent totality of all possible orders - how does the deferential sage survive deferring to chaos? Ostensibly, the sage must discriminate as much as we ordinary folk. The difference that makes all the difference is that the sage recognizes the arbitrariness, transitoriness and merely conventional status of such discriminations.

Only 'thises' and 'thats' exist, by virtue of their distinctive *de*. When discriminations are made, as perforce they must be, one treats or 'deems' things in the mode of a transitory discrimination. This involves the utterance of a 'that's it!' which deems something to be the case. The sage discriminates as is deemed necessary, always acting in a deferential mode. However, such discriminations are qualified in two important ways. First, the sage recognizes that such discriminations are conventional and transitory. Secondly, to the extent possible, even these discriminated items are engaged in the modes of unprincipled knowing, nonassertive action and objectless desire.

The Daoist posture of mirroring the world cannot be either dialectical or analytic, since both analysis and dialectic require a putative whole: the former in order to divide into parts, the latter in order to form the opposing parts into some synthetic whole. Neither the 'ten thousand things' nor the self which plies its way among them may be summed to a coherent whole. The Daoist way is *analogical*; that is to say, it involves the correlation of elements with presumed similarities of structure, character or function without the necessity of assuming a holistic context. Such a method emphasizes the *ad hoc* nature of any sorts of discrimination or organization.

The employment of correlativity without the necessity of positing a cosmic whole as background of one's ruminations is a defining characteristic of philosophical Daoism. From that insight follows the irrelevance of dialectical and analytic modes of discourse; and from the irrelevance of the dialectical and analytic modes of discourse follows the implausibility of precise concepts, or of univocal language. From the irrelevance of conceptual language derives the impossibility of having objects or explanations of those objects with any final integrity or comprehensiveness. This means that neither the world nor the self can constitute a coherent unity.

9 The transformation of things: *wuhua* (cont.)

We have seen thus far that the Daoist engages the world in a mirroring manner which accepts order to be a function of the focal activity of each item in the totality of things. In such a world, 'order' is the same as 'chaos'; that is, it is an indefinite set of overlapping orders. While the sage recognizes the hierarchical relationships which obtain among things, the *de* of the individual things must be deferred to because each thing also has parity with the others as an inimical and unsubstitutable defining condition.

We have tried to understand the notions of person and world in classical Daoism by articulating some of the consequences of the sage's act of mirroring which allows things to be seen in their original order(s). One way of doing this is to ask, as we have just done, 'what sort of being is it who engages a world constituted by a complex set of overlapping orders shaped by the individual perspectives or particular foci (*de*), of each of 'the ten thousand things'?' Responding to this question has led us to the notion of the deferential self characterized by the modes of

engagement identified as *wuzhi*, *wuwei* and *wuyu*. Another fruitful route toward understanding the Daoist version of the deferential self is by noting that the employment of the *wu*-forms as a means of mirroring the world as it is, has direct consequences for establishing the 'mood', 'temperament', or 'humour' with which the Daoist engages the ten thousand things.

The Daoist, by virtue of deferential activity, is characterized by a 'light-minded' or 'light-hearted' mood. As a popular translation of one of the chapter titles of the *Zhuangzi* has it, this mood is one of 'free and easy rambling'. Such a mood is often contrasted with the more serious-minded Confucian, and is even more dramatically contrasted with the 'high seriousness' of the Anglo-European culture. The dominant sensibility of Western philosophy is imbued with a commitment to a single-ordered world, hierarchically arranged with human beings near the top of the ladder ('a little less than the Angels'). The high-seriousness of the Western individual is an appropriate response to the fixed and permanent status of his world. Daoists, by contrast, respond to a more horizontal world of things possessed of an indefinite number of orders. Their's is thus a more flexible and light-hearted response. We propose to pursue this contrast between the 'serious' and the 'light-hearted' as means of highlighting the distinctive character of the Daoist world.

The first thing to be said has to do with the rather standard perception of Daoism as a relativistic mode of understanding. In the West, relativism is usually an epistemological doctrine: that is to say, 'relativity' is a theoretical notion. The relativities recognized are not thought to be ontologically constitutive of the way of things, and are seldom thought to involve practical consequences. Relativists do not normally wish to claim that the world itself actually exists in a number of different ways, but only that we have a number of different theories of the way of things, and that there is no satisfactory means of deciding which gets at the way things really are. Secondly, a consistent relativist must claim that nothing practically follows from relativism but inaction. If one tacitly or explicitly commits to one of a number of ways of acting, relativism has been practically abandoned. Thus, the issue of relativism in Western philosophy is, mainly, a red herring (see Relativism).

Philosophical Daoism avoids this sort of relativism by asserting a ground for parity by virtue of the continuity among things, associated with Zhuangzi's 'transformation of things' (*wuhua*). *Dao* is the total process of becoming which constitutes the ways of things. These things form 'worlds' characterizable from the perspective of each and every item in the total process. Given the uniqueness of each thing as a starting point, particulars must with reference to any given issue stand in hierarchical relationship. This is the ground of deference. All things defer, in this way or that, to everything else. This is why a correlative and hierarchical *yin-yang* vocabulary usually works to articulate relationships. We say usually because, given the porous nature and attendant vagueness of particular things and events, there are occasions on which the *yin-yang* language is not functional. As is stated in the *Yijing (Book of Changes)*, 'What *yin-yang* does not fathom is called inscrutability'.

The transformation of all things entails two important consequences. First, there are always myriad alternative postures which challenge the ultimacy of one's present configuration. Second, the processional nature of experience guarantees that one will in fact actually proceed through an indefinite number of such configurations. The sagely recognition of this fact is the source of Daoist light-heartedness.

With Daoism, and specifically the Zhuangzian variety, the issue of relativism is usually seen to be irrelevant. Though the assumption that Zhuangzi is a realist would doubtless be challenged by many scholars who would insist that he is an extremely subtle proponent of a kind of sceptical relativism, Zhuangzi's transformation of things seems to commit him to the belief that the world actually exists as a shifting set of ways of being, a myriad set of overlapping worlds, a chaos of 'thises' and 'thats', a multifarious congeries of orders. 'Chaos' (*hundun*), understood as the totality of all orders, names the way of things. Further, Zhuangzi seems to believe that there are crucial and direct practical consequences of such ontological pluralism. The deferential self, expressed through the modalities of the *wu*-forms, spontaneously engages in mirroring responses which take into account the *de* of the items or events he or she encounters. Thus, Zhuangzi's 'relativism' is seriously moderated at the level of practice since deference entails commitment. There are, therefore, direct practical consequences of mirroring the vast indifferent complex of the ways of things in a manner that allows one to see all things as viable candidates for deferential response.

The paradigm for Daoist light-heartedness turns out to be something like this:

> If people sleep in damp places, they ache at the waist and end up half-paralyzed, but is this the case with the loach? If they live in the trees, they tremble with fear, but is this the case with the ape?
>
> (*Zhuangzi* 2)

The paradigm of high seriousness on the other hand is something like:

What is sauce for the goose is sauce for the gander.

Daoist light-heartedness depends upon the coexistence of a plurality of viable world orders. On this view, the world - if by this we mean that *the* World is one, single-ordered, rational, coherent, internally consistent cosmos - is singularly humourless. Even if the totality is acknowledged to possess many orders, as long as there is any hint of a logical or axiological priority given to one or some orders *vis-à-vis* an other or other orders, the ground of any real light-mindedness or light-heartedness is undermined. This is the case because the notion of a privileged order implies a non-deferential, determinative stance. It is such a notion of superiority which cancels true light-heartedness. However, it is not simply a matter of taking up a variety of sympathetic stances. For Zhuangzi, one actually becomes all of the potential objects and beings with respect to which such stances may be taken:

> Before long, Master Lai fell ill. Wheezing and panting, he was on the brink of death. His wife and children gathered about him and wept. Master Li, having gone to enquire after him, scolded them, saying: 'Get away! Don't impede his transformations!'
>
> Leaning against the door, Master Li talked with him, saying: 'Extraordinary, these transformations! What are you going to be made into next? Where are you going to be sent? Will you be made into a rat's liver? Or will you be made into an insect's arm?…
>
> Now if a great ironsmith were in the process of casting metal, and the metal leapt about saying: 'I must be forged into a Mo Ye sword!' the great ironsmith would certainly consider it to be an inauspicious bit of metal. Now, if once having been cast in the human form, I were to whine: 'Make me into a human being! Make me into a human being!' the transformer of things would certainly take me to be an inauspicious person. Now once we take the heavens and earth to be a giant forge and transformation to be the great ironsmith, where ever I go is just fine. Relaxed I nod off and happily I awake.
>
> (*Zhuangzi* 6)

The transformative processes (*wuhua*) are not to be interfered with, but are to be met with deference. To this extent, the sage is in agreement with Faust who proclaims to Mephistopheles:

If I ever say to the moment, 'Hold! Thou art so fair!' then thou canst require my soul of me.

What distinguishes the life of the Daoist sage from that of the pleasure-seeking Faust lies in the difference between aggressive desiring and *wuyu*. For Faust each moment brings a new object of desire to be seduced, consumed or otherwise enjoyed, and then abandoned.

The Daoist neither demands constant transformation for the sake of the ever-new, nor objects to transformation, attempting to apply the brakes and hold onto the moment. The deferential self yields to the moment, without constraint.

Daoists such as Zhuangzi are light-hearted by virtue of being freed from the serious responsibilities entailed by 'being right', or 'having the truth'. Were one to seek a coherent theory to house Zhuangzi's teachings, he would risk constructing a platform from which he may proclaim (implicitly) the superiority of those teachings. And if we presume that Daoist light-heartedness is used in the defence of a vision of things which necessarily denies the validity of other visions, we have simply made any attempts at light-heartedness secondary to the 'true philosophical enterprise', namely, the defence of a particular way of envisaging things.

The character of light-heartedness lies in a felt incongruity or contradiction. The Daoist treats these incongruities as existing among things and events which are on a par with the others. The pluralist vision of Daoism plays upon the sense of the contradiction between one perspective and a myriad others: between Zhuangzi and a butterfly, among fishes, birds, cicadas and turtle doves, between men and monkeys. Light-heartedness is an essential means of teasing one into the recognition of the variety of perspectives permitted by the totality of existing things. The

need for allusiveness lies in the fact that one cannot fully appreciate the differences without some sense of the reality of those differences. However, one cannot confront these differences in too direct a manner; they may at best be hinted at.

We should note here that though the term ‘irony’ has often been used to name the Daoist form of light-heartedness, it is hardly an altogether appropriate one. There can be no real philosophic irony without something like the dialectic of tragedy and comedy as it developed in ancient Greece, and Zhuangzi’s doctrine of the transformation of things precludes the development of a tragic sense. The tragic sense is predicated upon loss. But the transformation of things guarantees that there is no final loss: there are only processes of transformation which realizes the becoming of what has not yet become.

Darwin, Charles Robert (1809-82)

Darwin's On the Origin of Species (1859) popularized the theory that all living things have evolved by natural processes from pre-existing forms. This displaced the traditional belief that species were designed by a wise and benevolent God. Darwin showed how many biological phenomena could be explained on the assumption that related species are descended from a common ancestor. Furthermore, he proposed a radical mechanism to explain how the transformations came about, namely, natural selection. This harsh and apparently purposeless mechanism was seen as a major threat to the claim that the universe has a transcendent goal.

Because Darwin openly extended his evolutionism to include the human race, it was necessary to re-examine the foundations of psychology, ethics and social theory. Moral values might be merely the rationalization of instinctive behaviour patterns. Since the process which produced these patterns was driven by struggle, it could be argued that society must inevitably reflect the harshness of nature ('social Darwinism'). Darwin's book has been seen as the trigger for a 'scientific revolution'. It took many decades for both science and Western culture to assimilate the more radical aspects of Darwin's theory. But since the mid-twentieth century Darwin's selection mechanism has become the basis for a highly successful theory of evolution, the human consequences of which are still being debated.

1 Scientific work

Darwin was born in 1809 in Shrewsbury, England. After a brief spell as a medical student he moved to Cambridge, where he received extra-curricular training in natural history and geology. Travelling on the survey ship HMS *Beagle* (1831-6), he studied the geology of South America and accepted what he took to be Charles Lyell's uniformitarian theory of geological change (see Geology, philosophy of §1). He proposed a new theory to explain the formation of coral reefs, and collected fossils and studied the geographical distribution of South American animals. In particular he was struck by the existence of distinct but related species of birds on the individual islands of the Galapagos group, off the west coast of South America.

Soon after his return to England, he became convinced that the Galapagos species could only be explained as the modified descendants of migrants from the mainland. Evolution theories were highly controversial at the time, but Darwin was soon a complete convert. He studied animal breeding and was led to the theory of natural selection. Having been active in the scientific life of London, in 1842 he moved to Down House in Kent, where he spent the rest of his life suffering from a debilitating illness. He kept up his studies of biogeography and produced a major taxonomic survey of barnacles. This work was intended to throw light on his theory, which remained unpublished until a similar idea was proposed by A.R. Wallace in 1858. *On the Origin of Species* was published at the end of 1859; following an intense controversy, the basic idea of evolution was accepted by the majority of scientists.

In *The Descent of Man* (1871) Darwin extended his theory to the human race. Much of his later scientific work centred on the application of his theory in botany, to explain the activity of climbing and insectivorous plants, and the relationship between flower structure and insect pollination. He also wrote a study of earthworms.

2 The evolutionary worldview

Conventional histories of the Darwinian revolution have assumed that, prior to the publication of the *Origin of Species*, everyone accepted that each species was designed by a wise and benevolent God. Darwin's materialistic theory thus upset a vision of a perfectly ordered universe. In fact, the idea of evolution had been widely discussed in the previous decades. Robert Chambers' *Vestiges of the Natural History of Creation* (1844), promoted the image of life progressing towards higher levels of physical and mental organization under the control of divinely implanted laws. Historians still debate the extent to which Darwin himself saw evolution as necessarily progressive. There was certainly an element of progressionism in his thinking, but his theory was built on different foundations and in later life he was unable to accept that the whole process was designed by the Creator. Darwin may have begun his work believing that the laws governing natural development were instituted by God, but he ended up seeing the universe as a scene of perpetual struggle and suffering.

Darwin argued that each population changes by adapting to its local environment. When members of a population migrate to new areas, they will adapt to the new conditions and thus come to differ from the parent group. If the

degree of difference becomes sufficient, the two populations would find it difficult to interbreed even if they came into contact, and would thus count as distinct species. Local varieties or subspecies are the first steps on the way to full speciation. The overall pattern of evolution must thus be visualized as an irregularly branching tree, not as the ascent of a ladder towards a fixed goal.

Darwin believed that evolution was an immensely slow process, and thus that it was unrealistic to expect ever to observe one species being transmuted into another. Opponents of the theory argued that we only observe minor changes within species, from which it is illegitimate to infer that change spead over a longer timespan will generate a new species distinct from the parent form. Darwin realized that the case for evolution would have to be argued by showing that the theory accounted for a range of otherwise inexplicable phenomena. He showed that the classification of species could be understood as a reflection of the tree-like model of genealogical relationships (see Taxonomy §§3-4). Each major taxon was founded by a single ancestral form which had developed some important evolutionary innovation; the descendants of this ancestor radiated out through the local adaptation of sub-populations, thus creating the genera and species we recognize today. Homologies such as the similar bone structures of the forelimb in humans, horses and bats were explained as adaptive modifications of similar structures inherited from a common ancestor. Relationships between dissimilar adult forms could often be traced in their early embryos, which were not subject to the same degree of modification. Darwin knew that evolutionary change could not be demonstrated from the fossil record, which often gave the appearance of sudden ’leaps’. He argued that the record is very imperfect, the ’leaps’ are in fact gaps concealing gradual evolutionary transformations. Once this factor was taken into account, the fossil record could be reconciled with the tree model. The geographical distribution of organisms could also be explained in terms of species migrating outward from their point of origin, adapting themselves to the new territories they entered (see Evolution, theory of).

3 Natural selection

The basic idea of evolution was accepted quite rapidly in the 1860s, although many people, scientists included, were unwilling to admit that the development of life on earth had no preordained goal. This meant that they were particularly worried about Darwin’s proposed mechanism of natural selection. In this theory, the species could not be regarded as having an underlying ’type’ on which all the individual organisms were modelled. The species was just the breeding population, and if the average structure of the individuals making up the population changed, then so did the species. The natural world could not be composed of a range of fixed, specific types or forms (see Species §2).

There was much debate over whether natural selection could be considered a *vera causa* or true cause capable of producing significant changes in species. Darwin knew that each component of the effect could be demonstrated individually, but doubted that selection could produce a new population incapable of interbreeding with the parental type within an observable timescale. For him, selection was a plausible mechanism of change, and probably the most important one - but he never ruled out the possibility of other mechanisms. Much of the initial opposition to the selection theory was based on an unwillingness to believe that the species does not have some sort of essence which prevents individuals becoming modified beyond a fixed range.

Darwin’s studies of domesticated animals convinced him that the individuals making up any population differ significantly among themselves. This is sometimes called ’random’ variation, because there seems to be no apparent purpose to the differences. Darwin knew that there was an underlying mechanism to explain the production of individual differences and their transmission through heredity, although his own explanation did not stand the test of time. Many of Darwin’s contemporaries found it difficult to accept that the variations which accumulate to give evolution could be produced by a process that imposed no fixed direction. They preferred to believe that the variations were directed along a predetermined channel by forces arising from within the organism, or were produced in response to the organism’s own purposeful activities. If characteristics acquired in response to new behaviour-patterns were inherited, this would give the rival evolutionary mechanism known as ‘Lamarckism’. Darwin himself accepted a subsidiary Lamarckian effect, but stressed the natural selection of random variation. Modern genetics has shown that acquired characteristics cannot be inherited and that mutations produce many different characteristics within a population. In the modern Darwinian theory, selection works by changing the frequencies of genes within the population (see Genetics).

Natural selection depends upon the elimination of those variant characteristics which are maladaptive, and the

superior reproductive fitness of those which confer some adaptive benefit. Following Malthus, Darwin believed that the tendency for a population to breed beyond the capacity of its food supply would lead to a 'struggle for existence' in which the least fit would be eliminated. This was what H. Spencer called the 'survival of the fittest'. Contrary to a popular anti-Darwinian argument, natural selection is not based on a tautology (the survival of those who survive), because fitness is defined in terms of the adaptation which enables an organism to live and breed more effectively. Darwin did, however, argue that there is a different mechanism, sexual selection, capable of enhancing those characteristics which, even if maladaptive, improve the organism's chances of reproducing. Thus the peacock has developed its large tail because this characteristic has become involved with the birds' mating behaviour - a bigger tail attracts peahens more effectively, and the reproductive advantage this confers outweighs the disadvantages of a large tail when escaping from predators.

4 Human origins

From the start, Darwin accepted that the human species would have to be included within the evolutionary worldview. If humans were to be treated as merely advanced animals, the mental and moral faculties traditionally seen as products of the soul would have to be explained as extensions of those faculties already possessed by animals. In his *Descent of Man* (1871) and *Expression of the Emotions in Man and the Animals* (1872), Darwin tried to justify this proposition and to explain how the human mind had developed so much further than those of our closest animal relatives. He did not believe that the mind was a *tabula rasa* or blank slate capable of indefinite modification by experience. Many mental activities are governed by instincts imprinted by evolution. He showed that many aspects of human behaviour, especially the way we express emotions, are relics of our animal ancestry. He also took seriously many stories that interpreted animal behaviour in anthropomorphic terms, thus providing apparent evidence that animals possess rudiments of even the highest mental and moral faculties.

Darwin accepted that the mental faculties were produced by the brain, and that the increased brain size of the 'higher' animals is reponsible for their increased intelligence and more complex behaviour. Many of his contemporaries assumed that evolution would inevitably produce a steady increase in the level of animal intelligence. In *The Descent of Man*, however, Darwin anticipated the modern position in which (since evolution is not inherently progressive) it is necessary to explain why the branch leading to humans has experienced a much greater expansion in intelligence than that leading to our closest cousins, the great apes. He argued that the distant ancestors of humans had stood upright as a means of walking on the open plains, while the apes had stayed in the trees. Human intellengence was a by-product of this change of habitat, produced as a means of exploiting the hand's ability to manipulate the environment.

Darwin argued that the higher animals exhibit social behaviour which provides the foundation for human moral values. Social behaviour is governed by instincts, and natural selection can act upon the variations in such instincts to promote useful behaviour patterns. Since our distant ancestors lived in social groups, we have inherited their social instincts, and our moral values are rationalizations of behavioural tendencies which we feel automatically. Modern efforts to explain some aspects of human behaviour in terms of biologically implanted instincts make use of the same argument (see Sociobiology).

Although Darwin anticipated some modern ideas on human evolution, he shared the prejudices of his own time and was convinced that Europeans were superior to other races and that modern industrial civilization is the highest expression of social evolution. His ideas were taken up by some social evolutionists who argued that here, as in the biological realm, progress would only result if individuals or races were left to struggle among themselves to determine which was fit enough to survive. This social philosophy came to be known as 'social Darwinism' - although one of its leading proponents, Herbert Spencer, was more a Lamarckian than a Darwinian. The claim that struggle was a spur to progress was developed in many other forms besides Darwin's theory of natural selection.

David of Dinant (*fl. c.*1210)

A twelfth- and early thirteenth-century philosopher who may have taught at Paris, David of Dinant was noted for a heretical, pantheistic view that identified God, mind and matter. None of his works survive intact, and we know of them primarily through the works of other authors. His major work, the Quaternuli, was condemned at Paris in 1210. His heretical views were influential enough to receive critical attention in the works of Albert the Great and Thomas Aquinas.

Very little is known for certain about David of Dinant's life. He was born, probably at Dinant, Belgium, but possibly in Dinan in Brittany, in the middle of the twelfth century. He may have taught at the University of Paris. A work of his identified as *Quaternuli*, perhaps the first word of the work's text, was condemned in 1210: all copies of it were to be brought to the Bishop of Paris and burned, and anyone discovered possessing the work after Christmas of that year was to be regarded as a heretic. This work may be identical to one attributed to David with the title *De Tomis hoc est de Divisionibus (On the Volume Known as 'On Divisions')*. David died most likely in the second decade of the thirteenth century, perhaps while a fugitive from France.

Some fragments of his writings appear to have survived, but his most distinctive views are to be gleaned from the accounts of his philosophical opponents. Chief among these are Albert the Great and Thomas Aquinas. Although Nicholas of Cusa also refers to David, he may have acquired his knowledge from reading Albert or Aquinas.

According to Aquinas, David divided reality into three parts, bodies, souls and eternal, separated substances. Bodies are composed of *hyle* or prime matter, souls are constituted from *nous* or mind, and eternal, separated substances are constituted from God. Albert and Aquinas both attribute to David the additional thesis that prime matter, mind and God are one and the same. It follows that God, mind and prime matter constitute all things, or, as Aquinas puts it, that everything is one essence. David's views thus contradict several doctrines of philosophical theology, defended particularly by scholastic philosophers; these include the doctrines that God is an immaterial being, that God is perfectly simple, having no parts or plurality of any kind, that the created world is separate from God, that God created the world out of nothing, and that human souls are not divine (see God, concepts of).

Aquinas claims that David's identification of God and prime matter was based on the argument that, if they were not identical, God would have to differ from prime matter by means of some differentiae. But if they possessed differentiae, God and prime matter would not be metaphysically simple, contrary to the assertion that they are simple. Aquinas, and apparently David, presuppose a theory of predication deriving from Aristotle by way of Porphyry's *Isagōgē* (see Porphyry). On that theory, questions concerning what natural kinds have in common and questions concerning how natural kinds differ from one another are to be answered by specifying the genera and differentiae of the respective natural kinds. Horses and humans, for example, are the same in genus insofar as they are both sensitive, animate corporeal substances, but different in species because horses possess the differentiae of being ungulate while lacking the differentiae of being bipedal and rational, and humans possess the differentiae of being bipedal and rational while not being ungulate. As reported by Aquinas, David's argument begins with the premise that God and prime matter are metaphysically simple, proceeds by inferring that they can thus have no differentiae (for the possession of any differentiae entails that its possessor is metaphysically complex), and concludes that because there is no specific difference between them, God and prime matter are identical.

Aquinas claims that David's argument is fallacious; it confuses *difference* with *diversity*. It is true that two distinct kinds of thing in the same genus must differ by means of some differentiae, but the same does not hold for kinds that share no genus in common. Although horses share something in common with humans, horses and humans share nothing in common with, for example, cerulean blue. There are no differentiae that distinguish colours from animate substances, but it does not follow that colours and animals are identical; they are simply diverse. Similarly, Aquinas argues, God and prime matter are diverse in themselves. In Aristotelian terms, prime matter is pure potentiality, having no actuality of its own, and God is pure actuality, a being having no unactualized potentiality.

Aquinas says that David 'most stupidly' identified God and prime matter (part 1, question 3, article 8, 'Whether God enters into the composition of other things').)

Davidson, Donald (1917-)

Donald Davidson's views about the relationship between our conceptions of ourselves as people and as complex physical objects have had significant impact on contemporary discussions of such topics as intention, action, causal explanation and weakness of the will. His collection of essays, Actions and Events (1980), contains many seminal contributions in these areas. But perhaps even greater has been the influence of Davidson's philosophy of language, as reflected especially in Inquires into Truth and Interpretation (1984). Among the philosophical issues connected to language on which Davidson has been influential are the nature of truth, the semantic paradoxes, first person authority, indexicals, modality, reference, quotation, metaphor, indeterminacy, convention, realism and the publicity of language.

1 Reasons and causes

Since 1963, with the publication of 'Actions, Reasons, and Causes', Donald Davidson's philosophical work has taken centre stage in analytic philosophy. He begins this essay with the question: what is the relation between a reason and an action when that reason explains the action by giving the agent's reasons for performing it? Prior to this essay, something like a consensus had formed in philosophy that this relationship was not causal. Discussion tended to centre around why it could not be causal and the consequences of its not being so.

Davidson's central purpose was 'to defend the ancient - and commonsense - position that rationalization is a species of causal explanation' (Davidson 1980: 3). A large portion of the essay is devoted to refuting various arguments, quite popular then, that purported to show that reasons could not be causes of the actions they rationalize. The arguments are too many and varied to be properly treated here, but in passing I note that they were largely inspired by remarks made by Wittgenstein and/or certain interpretations of Humean strictures on causation. Each argument proposes that a necessary condition for two items to interact causally is not satisfied by reasons and actions. Davidson replies to the leading arguments by showing in each case either that reasons and actions indeed satisfy the necessary condition in question or that the allegedly necessary condition for causal interaction is not necessary at all (see Action).

2 Events

Davidson's chief claim about events is that they are concrete particulars - that is, unrepeatable entities with location in space and time. He regards the mind-body problem as the problem of the relation between mental and physical events. He treats causation as a relation between events and he takes action to be a species of event, so that events comprise the very subject matter of action theory. He argues for the existence of events and for specific claims as to their nature.

In 'Causal Relations' (1980) Davidson argues that the most plausible interpretation of singular causal statements like 'The short circuit caused the fire' treats them as two-place predicate statements with their singular terms (in this case, 'the short circuit' and 'the fire') designating events. In 'The Individuation of Events' (1980), Davidson argues that an adequate theory of action must recognize that we can describe the same action differently. This seems crucial in making sense of perfectly natural claims like 'Jones managed to apologize in saying "I apologize"', wherein apparently one event is described both as an apology and as an utterance (see Events).

3 The mind-body problem

Consider claims (1)-(3):

(1) No mental event is a physical event.
(2) Some mental events cause physical events.
(3) The only causes of physical events are physical events.

Although much can be said in favour of each, together they clearly are inconsistent. The dilemma posed by the plausibility of each of (1)-(3) and by their apparent incompatibility is the traditional mind-body problem. Davidson's resolution of the dilemma is to abandon (1). Davidson's account accepts the following principles about the gap between the mental (*M*) and the physical (*P*) and about causation:

(4) There are no exceptionless psychological or psychophysical laws and in fact all exceptionless causal laws can be expressed in a purely physical vocabulary.
(5) Event *c* causes event *e* only if there is an exceptionless causal law which subsumes *c* and *e*.

It is commonly held that a property expressed by *M* is reducible to a property expressed by *P* only if there is an exceptionless law that links them. So, it follows from (4) that mental and physical properties are distinct. Thesis (5) says that *c* causes *e* only if there are descriptions *D* of *c* and D' of *e* and an exceptionless causal law *L* such that *L* and '*D* occurred' entail '*D* caused D''. Theses (4) and (5) entail that physical events have only physical causes and that all event causation is physically grounded.

Davidson shows that theses (2)-(5) can all be true if (and only if) mental events are identical to physical events. Say that an event *e* is a physical event just in case *e* satisfies a predicate of our basic physical sciences. These are the predicates appearing in exceptionless laws. Since only physical predicates (or predicates expressing properties reducible to basic physical properties) appear in such laws, it follows that every event that enters into causal relations satisfies a basic physical predicate. So, mental events which enter into causal relations are also physical events. The mental and physical are still distinct in so far as mental and physical events *so-described* are not linked by exceptionless law; but still mental events are physical events (see Anomalous monism).

4 Theory of meaning

Davidson's work in the philosophy of language began later than his seminal work in the philosophy of action. I will discuss primarily the first two essays in his 1984 collection, where he identifies an adequacy criterion for theories of meaning for natural languages, and then applies it critically to a number of then-prominent views about natural language. He also sketches a programme in which a Tarski-style truth theory plays the role of a theory of meaning which meets the criterion he initially articulated.

Like the nineteenth-century mathematician/philosopher Gottlob Frege, Davidson requires that we specify what every sentence means by exhibiting its meaning as a function of the meanings of its significant parts (and their arrangement in the sentence). Call any such theory for a language 'a compositional meaning theory' for that language (see Compositionality). That there must be a compositional meaning theory for natural languages, such as English, seems mandatory because natural languages are spoken by finite speakers without magical abilities, but natural languages themselves have an infinity of meaningful (and nonsynonymous) sentences, each one of which, at least potentially, a speaker understands (at a given time). This seems to require that our knowledge of meanings be based on (a finite number of) rules which determine from a finite set of semantical primitives what count as meaningful compositions, where an expression is semantically primitive if the 'rules which give the meaning for the sentences in which it does not appear do not suffice to determine the meaning of the sentences in which it does appear' (Davidson 1984: 9).

According to Davidson, a compositional theory of meaning for a language *L* is such that anyone who knows it is in a position to understand every sentence of *L*. By specifying the meaning of a sentence *S* in *L*, it is clear that what Davidson has in mind requires that the specification enable anyone who understands the language in which the specification is given, to understand *S*. Davidson's idea is that to provide a compositional meaning theory, we can produce a Tarski-like *truth theory* for *L* (see Tarski, A.). A theory is a truth theory for language *L* if and only if for each sentence *S* of *L*, the theory entails a 'T-sentence' of the form:

(T) *S* is true-in-*L* iff *p*,

where the sentence (T) is in a metalanguage *M* used to talk about *L*. An adequate theory of meaning for German, for example, should issue in theorems like (S):

(S) 'Schnee ist weiss' is true in German iff snow is white.

Davidson's twist on Tarski is that, instead of requiring (for a compositional meaning theory) that for each T-sentence the condition that '*p*' translates *S* is satisfied, Davidson merely requires that each T-sentence be true. While we thus can avoid the danger of circularity attendant on using the notion of 'correct translation' in characterizing what it takes to explain meaning, it may seem that the requirement of merely issuing in *true* T-sentences is too weak. All the 'iff' in a T-sentence requires is that the sentences surrounding it are either both

true or both false, so that the following is true, though not at all helpful about meaning:

(S*) ‘Schnee ist weiss’ is true in German iff grass is green.

Davidson points out, however, that the need for a *finitely stated* adequate theory of meaning to contain recursive apparatus plausibly would lead the theory to issue in (S) rather than (S*). Still, he imposes further constraints on an adequate meaning theory, as we will see in the next section (see Meaning and truth).

5 Radical interpretation

Davidson requires of the meaning-giving T-theory that it be empirically warranted under the practice of radical interpretation. This means that empirical considerations must be respected in choosing between different but true truth theories for, say, German, between a theory that issues in (S) and one that issues in the true but non-interpretive (S*). The favoured T-theory is to be selected on the basis of evidence plausibly available to a radical interpreter (RI), ‘someone who does not already know how to interpret utterances the theory is designed to cover’ (1984: 128). More particularly, an RI does not know the language they are trying to interpret and has no access to bilingual informants, prior dictionaries and the like. An RI can generally tell when an informant ‘holds-true’ a sentence even though they do not know the interpretation of the sentence (1984: 135). So, among the primary data for an RI are, for example:

(E) Kurt belongs to the German speech community, Kurt holds-true ‘Es regnet’ on Saturday at noon, and it is raining near Kurt on Saturday at noon.

Data like (E) are collected from a variety of speakers across a variety of times to confirm or support a generalization like:

(GE) For all speakers *x* in the German speech community, for any time *t*, *x* holds-true ‘Es regnet’ at *t* iff it is raining near *x* at *t*.

Sentences like (GE) provide evidence that the speakers of the community take some form of words to express a certain truth. Davidson, remarkably, does not consider anything else as potential evidence for interpreting another (1984: 135).

What licenses an inference from data like (GE) to the corresponding T-sentences? Davidson’s answer is that a principle of charity is presupposed. According to this principle, the favoured truth theory for a language *L* must entail T-sentences according to which most of the sentences that speakers of *L* hold true are true. Under radical interpretation, sentences held true must usually be true because interpretation is partly constituted by this principle of charity. So, once sentences like (GE) are collected, we can infer corresponding T-sentences via a principle of charity (see Charity, principle of §4; Meaning and understanding §2; Radical translation and radical interpretation §§7-10).

6 Indirect quotation

Indirect quotation attributions have long been known to possess features which frustrate the construction of satisfactory theories of meaning. For example, the inference (1)-(3) is an apparent instance of substitutivity of identity but it is invalid:

(1) Galileo said that the earth moves.
(2) The earth = the third planet from the sun.
(3) So, Galileo said that the third planet from the sun moves.

Davidson’s analysis of indirect discourse is driven by the desire to find a way of incorporating contexts like (1) into a truth theory for a language containing them (1984: 176). His proposal is that we analyse utterances of (1) as consisting of two distinct utterances:

(4) Galileo said that. [The earth moves.]

The first part of (4) is just a relational statement; the second part does not function semantically as part of what is said, but rather is there to serve as the referent of the demonstrative ‘that’ in an utterance of the first part. How

does this get the truth-conditions right? According to Davidson, (4) is true just in case what the speaker has referred to as ‘that’ is an utterance which *samesays* some assertive utterance by Galileo. ‘Samesays’ is treated somewhat casually: it is whatever relation between the utterances is required for things to come out intuitively right; two utterances samesay each other just in case they agree in content, import or purport.

Since paraphrase (4) of (1) contains a demonstrative, it is true or false only relative to a context of utterance. A typical utterance of (1) creates a context relative to which ‘that’ refers to an utterance of the bracketed sentence in (4). And since in most contexts the occurrences of ‘that’ in (1) and (3) refer to different utterances, (1)-(3) is invalid. It is also clear that (1)-(3) is not an instance of substitutivity of identity, since, on Davidson’s analysis, the singular terms ‘the earth’ and ‘the third planet from the sun’ do not even occur in (1) and (3).

Despite important virtues, Davidson’s account has not won anything like general acceptance. The literature is replete with objections: for example, Lepore and Loewer (1989). Some authors complain the account is too strong; others that it is too weak, and others that it fails to generalize, for example, to other propositional attitudinal ascriptions or to *de re* constructions (see Propositional attitude statements §3).

7 Adverbial modification

We began with Davidson on events. The strongest argument he advances for the existence of events and for his conception of their nature derives, surprisingly, from his views in the philosophy of language. Any theory of meaning for a language must embody a view of the relationship between language and reality. Davidson’s conviction is that a theory of meaning, by providing a view about this relationship, offers substantive answers to the various metaphysical questions about reality. In particular, it will require events in order to explain the semantic (logical) form of action, event and causal statements.

Consider the English sentence (1). One obvious candidate for its truth-condition is (2):

(1) John hit Bill.
(2) ‘John hit Bill’ is true if and only if John hit Bill.

In (2) language is both mentioned and used, and in this sense (2) ‘hooks up’ language to reality. This hook-up remains silent on the nature of reality. It simply tells us that the English sentence (2) requires for its truth that John hit Bill. Since an adequate theory of meaning must be finite (1984: 4-15), if we try to construct a theory for, say, English, we are forced to read structure into English sentences (see §4). There does not seem to be another way to generate infinitely many sentences from a finite vocabulary. But now consider sentences like (3)-(5):

(3) John hit Bill at six.
(4) John hit Bill at six in the bedroom.
(5) John hit Bill at six in the bedroom with the stick.

There are no specifiable limits upon the number of kinds of adverbial modifiers which can sensibly attach to these sorts of sentences. Therefore, treating each distinctively modified sentence as attributing between John and Bill a distinct *primitive* relation (such as hitting-at-six-in-the-bedroom) threatens to offend against the condition that the theory be finite. On the basis of considerations of this sort, Davidson proffers a proposal which reveals the common elements in these sentences, issues in the correct semantic truth-conditions, and validates the requisite implications - for instance, that (4) implies (3), and so forth. He takes sentences like (1) and (3)-(5) to harbour existential quantifiers ranging over events. The thesis that there are events is true because the best semantics for English requires quantification over them, as witnessed by their counterparts in first order logic ($1'$), and ($3'$)-($4'$) respectively:

($1'$) There is an event *e* and *e* is a hitting of Bill by John.
($3'$) There is an event *e* and *e* is a hitting of Bill by John and *e* occurs at six.
($4'$) There is an event *e* and *e* is a hitting of Bill by John and *e* occurs at six and *e* occurs in the bedroom.

This technique for discerning ontological commitments extends to all cases where quantification and predication are required in order to construct a satisfactory semantics for natural language. The method is a general method for doing ontology (see Adverbs; Ontological commitment).

8 Animal thought

According to Davidson, the capacity to think requires facility with language, so that only creatures with a language can think. He defends this controversial thesis in 'Thought and Talk' (1984) and 'Rational Animals' (1985). His argument begins by noting that ascriptions of propositional attitudes - belief, desire, intentions and the like - exhibit semantic opacity. In attributing, for example, to a dog the belief that the cat went up the tree we might wonder whether the propriety of this ascription would be affected were we to substitute for 'the tree' another expression that refers to the tree. If not, this would disclose that our attribution of belief to the dog falls short of literalness. If a dog holds a belief about a tree, it must do so under some description or other (1985: 475).

Davidson's main contention is that semantic opacity could be had only by connecting thought to language. He advances two different lines of argument to this conclusion. The first appeals to holism and it is of the form that since we could never have grounds for ascribing the required background beliefs to creatures without a language, we could never be warranted in ascribing to such creatures any thoughts at all. The argument is that since ascriptions of belief exhibit semantic opacity and since semantic opacity requires that we regard beliefs as possessing some definite intentional content and since the possession of a belief with a definite content presupposes 'endless' further beliefs, it follows that a creature to whom we are warranted in ascribing a belief is one possessing a sophisticated behavioural repertoire; and only linguistic behaviour exhibits the sort of complex pattern that might warrant such ascriptions.

Even if sound, this argument at most establishes that we are unlikely ever to have decisive evidence that a speechless creature has beliefs. Davidson, however, draws the stronger conclusion that 'unless there is actually such a complex pattern of behavior, there is no thought' (1985: 476). He is aware of this shortcoming in his argument and offers another. He argues that propositional attitudes require a dense network of beliefs, that 'in order to have a belief, it is necessary to have the concept of belief', and that 'in order to have the concept of belief one must have language', that is, one must be a member of a 'speech community' (1985: 478). How, it will be asked, does Davidson get from the ubiquity of belief and the claim that beliefs in turn require second-order beliefs to the conclusion that 'a creature must be a member of a speech community if it is to have the concept of belief' (1984: 170)?

Davidson argues as follows: the possibility of belief or thought generally depends on the concept of a representation that might be true or false; and a concept of truth and falsity includes some notion of an objective, public domain. And this, in turn, is possible only for an interpreter (1984: 170; 1985: 480). Davidson seems to hold that only utterances can afford the fine-grained structure required for attributing thought; for only a creature whose behaviour exhibits the kind of structure implied by a theory of meaning is a creature in which semantically opaque representations can make an appearance (see Animal language and thought).

9 Conceptual schemes

In 'On the Very Idea Of a Conceptual Scheme' (1984), Davidson argues that no good sense can be made of the idea that different people, communities, cultures or periods view, conceptualize, or make the world (or their worlds) in different ways; or of the distinction between conceptual scheme and empirical content. He associates conceptual schemes with sets of intertranslatable languages (1984: 191). Different conceptual schemes then correspond to non-intertranslatable languages. He then argues that it is hard to make sense of a total failure of translatability between languages (1984: 185). No one could be in a position to judge that others had concepts or beliefs radically different from their own (1984: 197).

In part, Davidson holds this view both because strong pressures arise from the very nature of radical interpretation (RI) and because 'all understanding of the speech of another involves radical interpretation' (1984: 125). Since RI, and therefore, all interpretation, has a holistic character, it makes no sense to ascribe a single belief to a person except against the background of a very large number of other beliefs. Furthermore, 'belief is in its nature veridical'. That it is so, can be seen 'by considering what determines the existence and contents of a belief' (1986: 432). It all comes back to Davidson's views about the conditions of correct attribution of beliefs and other propositional attitudes, that is, the possibility of RI. In interpreting another, an interpreter ventures hypotheses as to what in the circumstances in question causes the speaker to hold-true the sentence in question and this is supposed to provide them (normally) with the meaning of that sentence. In every case there will be many different

causal chains leading to the same utterance. An interpreter must choose one cause and does so by responding to something in the environment ('triangulating') and so converging on something that is a common cause both of their own response and of the utterance of the speaker, thereby correlating the two and thus giving content of the speaker's utterances (Davidson 1991: 159-60).

One immediate consequence is that an RI cannot find speakers to have beliefs if they themselves have no opinion as to their general truth and falsity. Given what beliefs are and how their contents are determined on this story, Davidson is committed to its being impossible that all a person's beliefs about the world might be false. An RI must therefore have beliefs about the world in order to succeed in ascribing beliefs about the world to others. But they also must find that others - if they have beliefs at all - largely agree with them in those beliefs. If Davidson is right, then the crucial aspect of his theory of RI is the importance of causality in determining what someone means or believes. We cannot 'in general fix what someone means independently of what he believes and independently of what caused the belief…. The causality plays an indispensable role in determining the content of what we say and believe' (Davidson 1986: 435). So, it is the central role of causation in the fixing of the contents of beliefs that ensures the truth of everything we believe is not in general 'logically independent' of having those very beliefs; and that others cannot differ too much from us about what it is they believe. The way in which the contents of beliefs are determined puts limits on the extent of falsity and diversity discriminable in a coherent set of beliefs. The method of RI 'enforces' on any successful interpreter the conclusion that a speaker's beliefs are largely true and largely like their own. Thus, the possibility of global scepticism is ruled out.

10 Against facts

In recent writings, for example, 'The Myth of the Subjective' (1989) and 'The Structure and Content of Truth' (1990), Davidson attempts to refute the claim that there are representations of reality. In the latter he argues against 'the popular assumption that sentences, or their spoken tokens, or sentence-like entities or configurations in our brains can properly be called "representations", since there is nothing for them to represent' (Davidson 1990). If facts do not make sentences true, then in what sense are they representations? On Davidson's approach to meaning no entities (facts, objects or events) correspond to sentences.

Davidson's main argument against facts and correspondence theories of truth appears in his 'True to the Facts' (1984). There we find the Great Fact argument that given certain plausible assumptions there is at most one fact. The assumptions are 'that a true sentence cannot be made to correspond to something quite different by the substitution of coreferring singular terms, or by the substitution of logically equivalent sentences' and from these assumptions one can prove that 'if true sentences correspond to anything, they all correspond to the same thing' (Davidson 1990: 303). Rightly or wrongly, Davidson takes these assumptions to embody traditional wisdom about facts (see Neale 1995). The main point is that if a context satisfies these two assumptions, then that context is truth functional. So, if a sentence is made true by some fact *f*, then every materially equivalent sentence is made true by *f* as well, and thus, *f* is the Great Fact (see Facts §2).

Daxue

Originally a chapter in the Liji (Book of Rites), one of the Five Classics in the Confucian tradition, the Daxue (Great Learning) has for centuries attained the status of a canon, arguably the most influential foundational text in East Asian Confucian humanism. When the great neo-Confucian thinker Zhu Xi grouped the Daxue with the Zhongyong (Doctrine of the Mean), another chapter in the Liji, the Confucian Analects and the Mengzi as the Four Books, its prominence in the Confucian scriptural tradition was assured. Since the Four Books with Master Zhu's commentaries became the required readings for the civil service examinations in 1313, and since Master Zhu insisted that the Daxue must be studied first among the Four, it has been widely acknowledged as the quintessential Confucian text.

Intent on presenting the case of Confucian moral and political agenda, the *Daxue (Great Learning)* establishes the three basic principles: enlightening the enlightened virtue, loving the people and abiding in the highest good. These neatly outline the basic concerns of the Confucian project: self-cultivation, social responsibility and ultimate human flourishing (see Confucian philosophy, Chinese). Enlightening the enlightened virtue is based on the premise that although human nature is naturally endowed with 'enlightened virtue' (*mingde*), a life-long moral self-cultivation is necessary so that our innate virtue will continue to be enlightened (see Self-cultivation, Chinese theories of). This paradox is central to Confucian teaching: while ontologically we are already sages, existentially we must always try to become sages. The second principle, 'loving the people', specifies that self-cultivation, far from being the quest for inner spirituality as a lonely struggle, necessarily involves communication with others. The self as a centre of relationships entails an ever-expanding network of human-relatedness. Loving the people, comparable to the Christian dictum of 'loving thy neighbour', is, according to Wang Yangming (1472-1529), a constitutive aspect of self-cultivation. However, Zhu Xi interpreted this particular principle significantly differently, as 'renew the people'. He was able to do so by changing one single word *qinmin* (to be close in the sense of loving and caring) to *xinmin* (to renew the people). This conflict of interpretation has profound implications for the style of governance implicit in the *Daxue*. The third principle, 'abiding in the highest good', does not raise philological issues, but the semantic significance is difficult to determine. Does it mean that the loftiest moral aspiration must serve as guidance for ordinary human existence, or that we must strive to approximate that which is always beyond our reach?

However, it is the eight steps in the *Daxue* that offer a holistic vision and a practical programme of self-cultivation, a way of learning to be human. These eight steps are: (1) investigation of things, (2) extension of knowledge, (3) authentication of the will, (4) rectification of the heart-and-mind, (5) cultivation of the person, (6) regulation of the family, (7) governance of the state and (8) universal peace. All are centred around self-cultivation (step 5). Thus, steps 1-4 constitute the inner dimension and 6-8 symbolize the outer manifestation of self-cultivation. The centrality of self-cultivation is unequivocal:

> From the Son of Heaven down to the common people, all must regard cultivation of the person as the root. There is never a case where the root is in disorder and yet the branches are in order. There has never been a case when what is treated with great importance becomes a matter of slight importance and what is treated with slight importance becomes a matter of great importance.
>
> (*Daxue*)

The sense of priority and sequence is crucial in the *Daxue*. The life orientation implicit in the text demands that a sense of direction (toward the highest good) can provide an anchorage for our moral self-realization. With this anchorage, we can have a fixed purpose which leads to tranquility of the mind. With tranquility of the mind, we can attain serene repose and only in serene repose can we cogitate. Only through cogitation can we fully embody the virtue that is originally ours. The Confucian project so conceived esteems learning, both as an acquisition of knowledge and as a process of self-transformation. However, it seems obvious that the acquisition of knowledge through the investigation of things is not empirical work for the sake of enhancing our cognitive intelligence; rather, it is the cultivation of moral knowledge as an integral part of our self-understanding.

The relationship between knowledge and morality raises challenging questions in Chinese philosophy. Is it possible that the investigation of things and the extension of knowledge naturally lead to the authentication of the

will? Must we begin the process of self-cultivation by making up our mind that the knowledge of the good is not empirically acquired but experientially confirmed? Should the investigation of things be understood as learning about the external world or should it be conceived as a form of self-reflection in the lifeworld? Understandably, the *Daxue* has become a basic reference and a primary source for numerous fruitful scholarly and philosophical debates in Chinese intellectual history.

However, it is beyond dispute that this approach to learning presupposes that the primary purpose of education is character building. The *Daxue*, as a form of adult education, offers a comprehensive programme for human flourishing. The programme, built upon the 'Elementary Learning', a highly ritualized guide to self-improvement, focuses on political leadership. In the modern context, the argument makes sense only if we think of it as addressed to rulers and their ministers, rather than to any ordinary person in search of moral guidance. Nevertheless, the strength of the argument lies in its assumptive reason that rulership, or leadership in general, proves to be identical with the moral self-cultivation of all people in ordinary human existence in the lifeworld. Indeed, how we exercise power and influence in the presumed privacy of our homes is politically meaningful and, thus, ought to be made publicly accountable. The *Daxue*, a brief essay of some 1,750 words, carries a profound message for cultivating politically significant ethical intelligence for the global community.

De

Across the corpus of pre-Qin philosophical literature, de*, conventionally translated as 'potency' or 'virtue', seems to have a fundamental cosmological significance from which its other connotations are derived. We begin from the pervasive assumption that existence is an uncaused, spontaneous process. It is* ziran*: so-of-itself. As a total field, this dynamic process is called* dao*; the individuated existents in this field - its various foci - are called* de*.*

In the Daoist literature, *de* denotes the particular as a focus of potency in this process conception of existence. *De* is any particular disposition of the totality. The *Daodejing* - literally, the classic of *dao* and *de* - states: 'The great *dao* is so expansive. It reaches in all directions. All of individuated existence arises because of it' (*Daodejing* 34) (see Daodejing).

When *de* is cultivated and accumulated, so that the particular is integrated utterly with its environments, the distinction between *dao* and *de* - between field and focus - collapses. *De* as an individuating notion is transformed into *de* as an integrating notion. The *Daodejing* 28 observes: 'One who possesses *de* in abundance is comparable to a new-born babe'. In this literature, both Daoist and Confucian, the infant, the uncarved block and the exemplary person are all metaphors for a condition in which one does not distinguish oneself from one's environments. These metaphors illustrate the assumption that any particular, when viewed in terms of its intrinsic relatedness, entails the full process of existence. Such being the case, because the babe is a matrix through which the full consequence of undiscriminated existence can be brought to focus and experienced, it can be used as a metaphor for the *de* which is *dao*.

The early Confucian tradition limited its concerns to the social and political problems of the human community. At this level, the cultivation of *de* is to overcome the discreteness and discontinuity of the inchoate self in the direction of continuity and social harmony. Through achieved excellence, one becomes a model for others and an object of deference. *De* is both 'potency' and 'virtue' in the sense that each person is a meaning-creating and meaning-disclosing focus. As one becomes extended in community through patterns of deference, one's capacity for valuation is proportionately increased. The human being is a world maker, and the greater one's proportions, the great one's efficacy as a maker of values.

The extension of *de* entails both an act of intending and the attraction of the support necessary to effect what is intended. The particular initiating the direction focuses this support as coextensive with its own particularity. At the same time, the particular becomes coextensive with 'other' by overcoming its particularity and accommodating the natural direction and volition of the 'other' to integrate them into its own field of interpretation. As artist, as communal leader, as teacher, one is able to organize one's natural, social and cultural environments and disclose their possibilities for productive harmony. One is able to manifest, interpret and display the local culture.

On the political level, the relationship between ruler and people is described in terms of *de*. To the extent that the ruler reaches out to become coextensive with the prevailing cultural propensities of the people, he expresses the values of the community. To the extent that he becomes culturally coextensive with them through deference, they come to share his values and moral insights, and he wins them over. If we consider agency, *de* means literally 'bounty' or 'beneficence' as it extends down from the ruler, and 'gratitude' as it is disclosed in the deference of the people. If, more appropriate to the Chinese tradition, we think situationally, *de* is the disposition of being both benefactor and beneficiary through productive, non-coercive communal relations. As the *de* of the people is manifest within the ruler's *de*, his potency is enhanced and he becomes the wind that bends the grass, the north star around which the other stars revolve, the maker and transmitter of culture to which other persons subscribe. It is in this sense that the emperor is the empire, and the patriarch is the family.

There is a coextensiveness of ruler and people in the sense that the ruler expresses the people through his government by accommodating their cultural proclivities and thus orchestrating an interpretation of culture that is both his and theirs. There is always, in this conception of *de*, a tension between attempting to maximize the possibilities for harmony provided by attending conditions, and the expression of an interpretation that does justice to one's own uniqueness and sense of appropriateness. It is the sensitive balancing of these forces that produces harmony within all human environments (see Culture; Sovereignty).

De Man, Paul (1919-83

De Man's work is among the most renowned and influential in American literary theory of the latter twentieth century, especially regarding literary theory's emergence as an interdisciplinary and philosophically ambitious discourse. Always emphasizing the linguistic aspects of a literary work over thematic, semantic or evaluative ones, de Man specifically focuses on the figurative features of literary language and their consequences for the undecidability of meaning. His extension of his mode of 'rhetorical reading' to philosophic texts also participates in the blurring of generic and institutional distinctions between literature and philosophy, a tendency pronounced in French philosophy of the latter twentieth century.

1 Deconstruction and Derrida

Paul de Man, born in Belgium and educated in comparative literature at Harvard, taught comparative literature at Cornell, Johns Hopkins and Yale universities. Associated with Jacques Derrida and deconstruction, and more generally with post-structuralism, de Man already exerted considerable influence through his teaching before the advent of deconstruction and his publication of an essay on Derrida. His association with Derrida and deconstruction is in part due to their subsequent friendship and colleagueship, but it is in part the artefact of the observer. De Man shares with Derrida the unrelenting attention to questions of language, and the rigorous practice of close reading of texts; with regard to deconstruction, he shares that practice's 'reversal' and 'reinscription' of assumed priorities - in de Man's case, the priority of meaning over the linguistic and tropological devices that ostensibly convey meaning, reversed and reinscribed by him as the irreducible textual productivity of tropes (metaphor, chiasmus, prosopopeia and so on) and other linguistic 'materiality' that leaves meaning suspended in undecidability and reading suspended in rhetorical repetitions and 'disfigurations' of the text before it. But he differs from Derrida in that he believes (as he argued in 'The Rhetoric of Blindness', in de Man 1971) that deconstruction is not something that one does to texts - as a philosopher, say, operating against the dominant grain of institutional philosophy - but rather something that texts do by themselves and to their readers. Thus de Man also de-emphasizes the 'institutional' aspect of Derridean deconstruction's 'reinscription' of problematic priorities back upon the institutional loci of their teaching and application, although in his later work issues of authority, ideology and critiques of falsehood are increasingly pronounced.

2 Literary theory

De Man's literary theory developed by way of studies of novels and poetry as well as philosophic texts, but it always displays several dominant features: drawing primarily upon romantic and modern authors, he foregrounds the rhetorical language of texts and explores its consequences for what texts actually, rather than apparently, mean; how they actually, if contradictorily, function; and how, ultimately, they may resist meaning and any satisfied aesthetic sense of their formal and structural workings. In essays from the 1950s and 1960s, borrowing from European phenomenology and its terminologies of consciousness, intentionality, temporality and being, de Man accents the difference and tension between poetic language's power to posit and imagine linguistically determined conditions on the one hand, and literature's false attractions - representational and nostalgic - toward natural objects and ontological being on the other. His highly influential essay 'The Rhetoric of Temporality' (1969), which also signals his turn toward a focus upon rhetorical language, analyses as allegory the perpetual reinstating of a temporal distance between a subject and its origin, and as irony the unbridgeable discrepancy between a linguistic and an empirical self. In his equally influential collection *Blindness and Insight* (1971), de Man studies European writers and critics (Husserl, Heidegger, Binswanger, Lukács, Blanchot, Poulet, Nietzsche, Derrida, Baudelaire, Mallarmé) to demonstrate the priority of a text's 'insight' or self-knowing 'rhetoricity' over the 'blindness' of its readers who unwittingly ('blindly') repeat the text's structure and statement when they believe they are critically most distant from them. De Man here extends the category of the 'literary' to include philosophic texts as well as literature conventionally construed: 'any text that implicity or explicitly signifies its own rhetorical mode and prefigures its own misunderstanding as the correlative of its rhetorical nature' (1971: 136). *Allegories of Reading* (1979) expands the sense of rhetoricity as the undecidability between literal and figurative meanings of a text, in a series of analyses of the 'allegories' or figurative narratives of mis- and non-understanding that generate themselves in response to the textual figures and rhetoric of such authors as Yeats, Rilke and Proust but also Nietzsche and above all, Rousseau. In this book as well as in subsequent essays on

Wordsworth, Shelley, Baudelaire and others (collected in *The Rhetoric of Romanticism*, 1984), de Man increasingly emphasizes what he calls the 'materiality' of language, its 'inscription', meaning the nonsemantic, noncognitive dimensions of language that subtend all linguistic acts not only as grammar, for example, subtends semantics, but also as the sheer positing of linguistic signifiers and their frequent interference with or 'disfiguring' of signification subtend all possible logical, grammatical or semiotic codifications and decodings of language. This latter aspect of his work marks de Man as post-structuralist, in resolutely refusing any reduction of language and signification to code.

3 Philosophical critique

Throughout his work de Man draws with seeming indifference from philosophy as well as literature and criticism to develop his literary theory. This leads to a deliberate blurring of distinctions between the two kinds of discourse, which is perhaps an easy and uncontroversial manoeuvre when he treats authors who themselves challenged or ignored the difference (Pascal, Rousseau, Nietzsche, Benjamin, Heidegger, Blanchot), as, for example, in his reconfounding of Rousseau's confusing differentiations between natural, fictional and historical conditions. But in a number of essays, some left unfinished by him and just recently (1996) published, de Man attempts a more frontal critique of certain assumptions and goals of mainline Western philosophy. Writing on Locke, Kant and Hegel, de Man not only signals the tropological substratum that enables but also destabilizes the establishment of certain philosophic concepts (for example, a 'ground'), he also calls into question the claims that there is thought that is distinguishable from - nobler, more ideal than - language in its materiality (Hegel), and that language ought to or can be modelled on phenomenal and cognitive presentation of meaning from the world (Kant). He subsumes the 'matching' of language, and with it of grammar and logic, to a phenomenal-cognitive model of nature and its human experience, under the names of an 'aesthetic formalization' or 'aesthetic ideology'; and he criticizes it in the name of language's tropological, material and ultimately nonsignifying otherness from all aesthetics and other rational-logical extensions that would establish a truthful continuity between the world and language or vice versa. De Man's work, then, a collection of radical, unique and often incisive readings of literary and philosophic texts that remains (1997) unconsidered by most professional philosophers, offers a view of language and textuality that is an anti-theory of philosophy as well as a controversial theory of literature.

Godzich, W. (1983) 'Caution! Reader at Work!', introduction to 2nd edn of P. de Man, *Blindness and Insight*, Minneapolis, MN: University of Minnesota Press. (A useful introduction, distinguishing de Man's 'reading' from other critical and interpretive practices.)

Godzich, W. (1986) 'The Tiger of the Paper Mat', foreword to P. de Man, *The Resistance to Theory*, Minneapolis, MN: University of Minnesota Press. (Especially helpful in sketching the philosophical background and importance of de Man's use of resistance.)

Hamacher, W. (1989) 'LECTIO: De Man's Imperative', in L. Waters and W. Godzich (eds) *Reading de Man Reading*, Minneapolis, MN: University of Minnesota Press. (The most incisive analysis thus far of the active or performative aspects of 'reading' in de Man's writings.)

Jacobs, C. (1989) 'Allegories of Reading Paul de Man', in L. Waters and W. Godzich (eds) *Reading de Man Reading*, Minneapolis, MN: University of Minnesota Press. (The best example of deploying de Man's reading of allegory to read de Man on allegory.)

De Morgan, Augustus (1806-71)

Augustus De Morgan was an important British mathematician and logician. Much of his logical work was directed to expanding the traditional syllogistic theory, and to meeting the objections of Sir William Hamilton and his allies to the techniques he used. More important for the future of logic, though, was De Morgan's work in two areas: the logic of complex (compound) terms, in which he essentially developed the theory of Boolean algebra, and his introduction of the logic of relations as a serious topic for formal logic. His work on probability logic, while flawed, was also significant.

Augustus De Morgan was born in Madura, India. He grew up in England and graduated from Trinity College, Cambridge in 1827. His mathematical abilities were such that he was appointed Professor of Mathematics at the newly founded University of London (now University College) the following year. He resigned on grounds of principle in 1831, but returned in 1836. He then held his professorship for thirty years, resigning, once again for reasons of principle, in 1866.

De Morgan was an amazingly prolific writer for both specialist and general audiences. As a mathematician, he clarified the concepts of mathematical induction and of limits, and he proved an important result about infinite series. He made significant contributions to the foundations and philosophy of algebra, and was deeply interested in the history and bibliography of mathematics. He is best known for the logical works which he published from 1847 to 1862. Their interpretation is difficult, however, for De Morgan's unusually fertile imagination was often constrained by being placed at the service of an essentially conservative attempt to extend the theory of the syllogism.

Much of De Morgan's published work arose from his highly publicized controversy with Sir William Hamilton over the quantification of the predicate. At first this dispute concerned Hamilton's charge that De Morgan had plagiarized from Hamilton's work, but it was soon resolved in De Morgan's favour. It then became a lively controversy over the comparative merits of Hamilton's and De Morgan's modifications of traditional logic. To the modern reader, much of this dispute seems very dated. However, De Morgan's analyses of categorical propositions remain interesting. He introduced into logic the concept of the universe of discourse, and he allowed that for each term, '*X*', there would also be its contrary, '*x*'. With this notation, there are eight possible categorical propositions:

(1) All *X*s are *Y*s
(2) All *x*s are *y*s
(3) All *X*s are *y*s
(4) All *x*s are *Y*s
(5) Some *X*s are *Y*s
(6) Some *x*s are *y*s
(7) Some *X*s are *y*s
(8) Some *x*s are *Y*s

All except (4) and (6) can be expressed as traditional categorical propositions using only '*X*' and '*Y*'; (4), however, must be stated as 'Everything is *X* or *Y*', and (6), its negation, as 'Some things are neither *X*s or *Y*s'. De Morgan devised an ingenious 'spicular' notation for expressing these forms, which allowed him to state concisely the rules of inference for this enlarged system.

If De Morgan's syllogistic modifications look backwards, two facets of his work look forwards. The first is the often neglected logic of complex (or compound) terms in his *Formal Logic* (1847: ch. 6). In this treatment, '*XY*' stands for the 'conjunction' of the classes *X* and *Y*, and '*X*, *Y*' stands for their 'disjunction'. The most familiar feature of this section is 'De Morgan's laws':

$\text{non-}(XY) = x, y$ and $\text{non-}(X, Y) = xy$

However, there is much more to this section than these laws; it contains, in essence, the full theory of Boolean algebra. In fact, De Morgan's system is probably closer to modern Boolean algebra than Boole's (see Boole, G.;

Boolean algebra).

One interesting feature of De Morgan's account is his characterization of conjunction and disjunction. Where '*X*)*P*' stands for 'Every *X* is *P*', the Conjunctive Principle is

$$\text{If } X)P \text{ and } X)Q \text{ then } X)PQ,$$

and the Disjunctive Principle is

$$\text{If } P)X \text{ and } Q)X \text{ then } P,Q)X.$$

These laws for conjunction and disjunction (intersection and union) today provide the basis for one of the two common formulations of Boolean algebra.

De Morgan's other main contribution to logic was his powerful logic of relations. Philosophical considerations led him to give a relational analysis of all propositions; and this resulted, in turn, in his formal logic of relations ('On the Syllogism IV', 1860).

Where '*X*' and '*Y*' are singular terms, and '*L*' and '*M*' are relational expressions, De Morgan used the following notation:

$X..LY$ *X* is an *L* of *Y*
$X.LY$ *X* is not an *L* of *Y*
$X..lY$ *X* is a non-*L* of *Y*
$X..LMY$ *X* is an *L* of an *M* of *Y*
$X..LM'Y$ *X* is an *L* of every *M* of *Y*
$X..L,MY$ *X* is an *L* of none but *M*s of *Y*
$L))M$ *L* is included in *M*

De Morgan stated a great many relational identities, such as

$$\text{not}(L^{-1}) = l^{-1}$$

and

$$(LM)^{-1} = M^{-1}L^{-1}$$

One of De Morgan's most interesting propositions is 'Theorem K':

$$\text{If } LM))N, \text{ then } nM^{-1}))1,$$

for which he provided an elegant demonstration.

De Morgan seemed most interested in applying his logic of relations to the analysis of the syllogism. Thus, while he hinted at some of the elaborations of this logic which would come later, he did not carry them out, nor did he work further on the logic of relations.

Some of De Morgan's other ideas, such as that of the numerically definite syllogism, have had only a minor impact on the history of logic. However, his attempt to include within logic the theory of probability, conceived of as the theory of rational degrees of belief, was of considerable importance. His concern was in calculating the probability of the conclusion of a logically valid argument whose premises are merely probable. Within this domain, he emphasized traditional problems about the uses of authority and testimony in argument. While his analyses of such cases were insightful, they were often flawed by a failure to require the stochastic independence of the elements of a conjunction when replacing the probability of a conjunction by the product of the probabilities of its conjuncts (see Probability theory and epistemology).

De re/de dicto

*'*De re*' and '*de dicto*' have been used to label a host of different, albeit interrelated, distinctions. '*De dicto*' means 'of, or concerning, a dictum', that is, something having representative content, such as a sentence, statement or proposition. '*De re*' means 'of, or concerning, a thing'. For example, a* de dicto *belief is a belief that a bearer of representative content is true, while a* de re *belief is a belief concerning some thing, that it has a particular characteristic.*

Consider the following example:

John believes his next-door neighbour is a Buddhist.

This statement is ambiguous. Construed de dicto*, it is true in the following circumstance. John has never had any contact with his next-door neighbour. Nevertheless, John believes that his next-door neighbour is bound to be a Buddhist. Construed in this* de dicto *fashion, the statement does not attribute to John a belief that is distinctively about a particular individual. In contrast, construed* de re*, it does attribute to John a belief that is about a particular individual. For example, construed* de re*, the statement is true in the following circumstance. John encounters his next-door neighbour, Fred, at a party without realizing that Fred is his next-door neighbour. On the basis of his conversation with Fred, John forms a belief about the individual who is in fact his next-door neighbour to the effect that he is a Buddhist.*

1 The different distinctions

'*De dicto*' means 'of, or concerning, a dictum'. '*De re*' means 'of, or concerning, a thing'. Roughly, a *de dicto* belief is a belief that a bearer of representative content (that is, a statement, sentence, proposition or such like) is true, while a *de re* belief is a belief concerning some thing, that it has a particular characteristic. (I)-(IX) below are a number of different distinctions that have been described as *de re*/*de dicto* distinctions in the literature.

(I) In the case of modality and belief we can draw scope distinctions. Consider the following sentences:

(1) Every effect necessarily has a cause.
(2) Joan believes her husband is an axe murderer.

(1) and (2) manifest a scope ambiguity. (1) is ambiguous between:

(1′) [squ] (if *e* is an effect then *e* has a cause),

in which the entire sentence 'If *e* is an effect then *e* has a cause' falls within the scope of 'Čsqu;'; and:

(1*) If *e* is an effect, [squ] (*e* has a cause),

in which only the part '*e* has a cause' falls within the scope of 'Čsqu;'. (2) may, likewise, be disambiguated as:

(2′) Joan believes that her husband is an axe murderer

or:

(2*) Joan's husband is believed by Joan to be an axe murderer.

(1′) and (2′) give the *de dicto* readings of (1) and (2). (1*) and (2*) give their *de re* readings. According to (1′), it is impossible for something to be an effect without having a cause - something few would dispute. According to (1*), it is impossible for anything which is an effect not to have been caused - a much more controversial claim. (2′) implies that Joan has the disconcerting belief she could express by uttering, 'My husband is an axe murderer'. (2*) implies that Joan has a less disconcerting belief. According to (2*), she believes that someone, whom, perhaps unbeknownst to her, she is married to, is an axe murderer (see Propositional attitudes §2).

(II) A sentence expresses a *de re* modality provided that some object essentially features in its truth-condition in the following sense: its truth-value depends on the characteristics that the object might have. For example, the

sentence ‘Possibly Fred is a Buddhist’ expresses a *de re* modality because its truth-value depends on whether a certain individual, Fred, could have the characteristic of being a Buddhist.

(III) Some hold that predicates such as ‘is necessarily human’ or ‘is possibly six feet tall’ attribute a special kind of property known as a modal property. A *de re* modal attribution attributes a modal property. For example, ‘John is necessarily human’ expresses a *de re* modal attribution if it attributes to John the modal property of being necessarily human.

(IV) Another *de re*/*de dicto* distinction depends on the distinction between rigid and non-rigid designators. Proper names such as ‘Napoleon’ are said to be rigid designators because they designate the same thing in any possible situation in which they designate at all (see Proper names §2). According to this way of drawing the distinction, a modal sentence expresses a *de re* modality if it contains a rigid designator falling within the scope of a modal operator. For example, ‘It might have been the case that Napoleon spoke Chinese’ expresses a *de re* modality, in contrast to ‘It might have been the case that the most famous French general spoke Chinese’.

(V) Quine (1953) insists that modalities are invariably relativized to a description in the following sense. We cannot say that something necessarily or possibly has a characteristic absolutely: we can only say that something necessarily or possibly has a characteristic relative to a description. Bill Clinton is necessarily a president relative to the description ‘42nd President’. He is contingently a president relative to the description ‘husband of Hillary’. In Quine’s view all modalities are *de dicto*. *De re* modalities, if, contra Quine, they existed, would be those not relativized to a description.

Some further distinctions taken to be distinctions between the *de re* and the *de dicto* are illustrated in application to belief.

(VI) It has been argued that we should distinguish between two kinds of belief. Having a *de dicto* belief amounts to standing in a two place relation to a dictum. Having a *de re* belief amounts to standing in an at least three place relation to an object and a property. Suppose John believes that all prominent politicians are wealthy. In consequence, without knowing who is president, he believes that the president is wealthy. In that case, John will have a *de dicto* belief in virtue of standing in the two place belief relation to the sentence ‘The president is wealthy’.

Now suppose that Sally meets Bill Clinton, and judges from the cut of his clothes that he is wealthy. Whether or not she believes he is president, Sally believes of the president that he is wealthy. According to this way of distinguishing *de re* from *de dicto* beliefs, Sally stands in the three place belief relation to the president and the characteristic of being wealthy.

(VII) In another way of distinguishing between *de re* and *de dicto* beliefs, a *de re* belief is about a particular individual or individuals, whereas a *de dicto* belief is general. Sally’s belief about the president that he is wealthy is a belief about a particular individual to the effect that he is wealthy. On the other hand, John’s belief that the president is wealthy is the general belief that whoever occupies the presidency is wealthy.

(VIII) A different epistemic distinction between *de re* and *de dicto* beliefs is as follows. In contrast with a *de dicto* belief, in order to have a *de re* belief one must be epistemically acquainted with the subject of one’s belief: one must know who, which or what it is.

(IX) A final distinction is that between object-dependent and object-independent beliefs. Sally sees a cat and forms the belief that she expresses by uttering, ‘That cat has mange’. Some say that she cannot hold this belief about the cat unless it exists. If so, her belief is object-dependent. It is sometimes held that *de re*, as opposed to *de dicto*, beliefs are object-dependent in this sense.

2 Relationships between the different distinctions

Consider the following examples:

(3) [squ] (the subject of Gance’s best-known film was human).
(3′) The subject of Gance’s best-known film is such that [squ] it was human.

Abel Gance’s best-known film was about Napoleon. According to distinction (I) above, sentence (3) expresses a

de dicto modality and (3′) a *de re* modality. ‘The subject of Gance’s best-known film’ falls within the scope of ‘Čsqu;’ in (3), and outside the scope of that modal operator in (3′). So Napoleon does not essentially feature in the truth-condition of (3). Hence, distinctions (I) and (II) above would agree in counting (3) as a *de dicto* modality. Since ‘the subject of Gance’s best-known film’ falls outside the scope of ‘Čsqu;’ in (3′), (3′) is true if and only if it is impossible for Napoleon to have been nonhuman. So (I) and (II) likewise agree in counting (3′) as a *de re* modality.

Distinction (III) has it that sentences expressing *de re* modalities attribute modal properties. The truth-value of (3) does not depend on Napoleon having the modal property of being necessarily human. Arguably, the truth-value of (3′) does depend on his having that modal property. So (III), like (I) and (II), decrees that (3) is a *de dicto* modality and (3′) is *de re*.

‘The subject of Gance’s best-known film’ is a non-rigid designator because it designates different things in different possible situations. Since ‘the subject of Gance’s best-known film’ falls within the scope of the modal operator in (3), (IV) deems (3) to be a *de dicto* modality. In (3′), ‘the subject of Gance’s best-known film’ falling outside the scope of ‘Čsqu;’ has the same effect as replacing ‘the subject of Gance’s best-known film’ with a rigid designator such as ‘Napoleon’ in (3).

(3*) [squ] (Napoleon was human).

The truth-value of (3*) depends on whether the actual referent of ‘Napoleon’ might have been nonhuman. According to (IV), (3*) expresses a *de re* modality for basically the same reason that (3′) does according to (II) and (III).

Distinction (V) implies that a modality is *de dicto* if it is relativized to a description. Otherwise, it is *de re*. (3) is true if and only if nothing could be nonhuman which satisfies the description ‘the subject of Gance’s best-known film’. In Quine’s sense the modality in (3) is relativized to a description, and is an example of a *de dicto* modality. In contrast, since the definite description in (3′) falls outside the scope of the modal operator, the truth of (3′) requires that the individual who actually satisfies that definite description must be human. (3′) is true if and only if Napoleon, the individual actually referred to by ‘the subject of Gance’s best-known film’, must be human. (V) implies that (3′) is a *de re* modality.

Now consider:

(4) John believes that the president is wealthy.
(4′) The president is such that Sally believes he is wealthy.

According to (VI) above, a *de dicto* belief relates a believer to a proposition, sentence or statement, whereas a *de re* belief relates a believer to something that may be extralinguistic. John’s *de dicto* belief that the president is wealthy relates John to the sentence ‘The president is wealthy’. The *de re* belief attributed to Sally by (4′) relates her to Bill Clinton.

Since Sally’s *de re* belief about the president relates her to Clinton, she could not have that belief unless Clinton exists. Hence, the belief attributed to Sally by (4′) turns out to be object-dependent in conformity with distinction (IX). Moreover, if Sally’s *de re* belief about the president relates her to Clinton, it is about a specific individual. Hence, it is *de re* in conformity with (VII). Since Sally knows who it is she believes to be wealthy, her belief is also *de re* in the terms of distinction (VIII).

Death

Reflection on death gives rise to a variety of philosophical questions. One of the deepest of these is a question about the nature of death. Typically, philosophers interpret this question as a call for an analysis or definition of the concept of death. Plato, for example, proposed to define death as the separation of soul from body. However, this definition is not acceptable to those who think that there are no souls. It is also unacceptable to anyone who thinks that plants and lower animals have no souls, but can nonetheless die. Others have defined death simply as the cessation of life. This too is problematic, since an organism that goes into suspended animation ceases to live, but may not actually die.

Death is described as 'mysterious', but neither is it clear what this means. Suppose we cannot formulate a satisfactory analysis of the concept of death: in this respect death would be mysterious, but no more so than any other concept that defies analysis. Some have said that what makes death especially mysterious and frightening is the fact that we cannot know what it will be like. Death is typically regarded as a great evil, especially if it strikes someone too soon. However, Epicurus and others argued that death cannot harm those who die, since people go out of existence when they die, and people cannot be harmed at times when they do not exist. Others have countered that the evil of death may lie in the fact that death deprives us of the goods we would have enjoyed if we had lived. On this view, death may be a great evil for a person, even if they cease to exist at the moment of death.

Philosophers have also been concerned with the question of whether people can survive death. This is open to several interpretations, depending on what we understand to be people and what we mean by 'survive'. Traditional materialists take each person to be a purely physical object - a human body. Since human bodies generally continue to exist after death, such materialists presumably must say that we generally survive death. However, such survival would be of little value to the deceased, since the surviving entity is just a lifeless corpse. Dualists take each person to have both a body and a soul. A dualist may maintain that at death the soul separates from the body, thereby continuing to enjoy (or suffer) various experiences after the body has died.

Some who believe in survival think that the eternal life of the soul after bodily death can be a good beyond comparison. But Bernard Williams has argued that eternal life would be profoundly unattractive. If we imagine ourselves perpetually stuck at a given age, we may reasonably fear that eternal life will eventually become rather boring. On the other hand, if we imagine ourselves experiencing an endless sequence of varied 'lives', each disconnected from the others, then it is questionable whether it will in fact be 'one person' who lives eternally.

Finally, there are questions about death and the meaning of life. Suppose death marks the end of all conscious experience - would our lives be then rendered meaningless? Or would the fact of impending death help us to recognize the value of our lives, and thereby give deeper meaning to life?

1 Analysis of death versus criterion of death

The most fundamental philosophical question about death is the question concerning its nature or essence - 'What is death?'. When philosophers offer answers to this question, they may be said to be defining death. It is important to recognize that two distinct projects may be confused under the single name 'defining death'. The first is a project in conceptual analysis which tries to give an account of the nature of death. Since death is the event that takes place when an organism dies, one way to explain the nature of death would be to formulate a definition of '*x* dies at *t*'. If successful, such a definition would tell us what we mean when we say that something dies, and thus reveal the nature of death. Among the most popular proposals is:

(D1) *x* dies at $t =_{df.} x$ ceases to be alive at *t*

A definition of this sort is successful if it is true. A fully adequate definition of death would display the structure of the concept of death.

The second (or 'criterial') project is one of public policy. For many practical purposes, it is important to have agreement on the question of whether a person is dead or alive. Furthermore, for practical purposes, it is important that there should be agreement about the time of death. Even if we agreed that (D1) is true, we might still be in grave doubt about whether certain people are dead. For example, consider a person whose brain has been

irreparably destroyed in an accident, but whose blood is being oxygenated and circulated by life-support mechanisms. Since it is unclear whether people such as this have ceased to be alive, it is unclear whether they are dead. Those who engage in the criterial project try to formulate a criterion of human death that is relatively easy to apply. Such a criterion would pick out an observable change that occurs around the time on which most would agree that humans die. The proposal would then be that this change (for example, cessation of electrical activity in the brain, cessation of respiration, cessation of heartbeat, and so on) should be taken to be the legal mark of death. If the proposal were accepted, then medical personnel and undertakers, among others, could appeal to this criterion as a legal defence.

Conceptual analysis would yield a necessary truth about the structure of the concept of death. The search for such analyses fits into a philosophical tradition going back to Plato and Aristotle. It resembles attempts to analyse such concepts as knowledge, causation, goodness and truth, so the analytical project is classically philosophical. The criterial project, if successful, would lead to a contingently useful criterion of human death. If it were accepted by the courts, it might remain in use for decades (until medical technology made it obsolete). But at best it would be a contingent principle with just temporary and practical value. The project itself requires knowledge of medical details and legal precedents, but does not seem to be a project for which philosophers are especially well qualified.

2 Death as separation of body from soul

In the *Phaedo*, Plato has Socrates say:

> Is it [death] not the separation of soul and body? And to be dead is the completion of this; when the soul exists in herself, and is released from the body and the body is released from the soul, what is this but death?
>
> (*Phaedo* [Jowett, 1937 vol. 1]: 447)

These remarks suggest a view about the nature of death:

(D2) *x* dies at $t =_{df.}$ x's soul separates from *x*'s body at *t*

This is problematic, one problem being that (D2) entails that if a thing is to die, it must have a soul. Yet many find it hard to believe that plants (which clearly can die) have souls. Similarly, many find it hard to believe that every living cell has a soul, and yet cells can die.

Many philosophers accept a materialist conception of people. They think that people are material objects - their bodies. Materialists of this sort think that people have no souls. Unless they want to say that people never die, (D2) is clearly unacceptable to such materialists (see Materialism).

3 Death as the cessation of life

The most popular analysis of the concept of death is expressed by (D1). One problem with (D1), however, is its obscurity. There is great controversy about the concept of life. Some claim that to be alive is to be able to engage in life processes, such as nutrition, respiration, and reproduction. Others say that life requires the presence of a soul or some other animating substance. Still others define life by appeal to the notion that living things are able to resist the force of entropy. A number of incompatible accounts of the nature of life have been proposed, but none enjoys universal acceptance. Hence, it is not entirely clear that we know precisely what we mean when we say that something is alive. Since in (D1) death is defined by appeal to the concept of life, (D1) inherits the obscurity of the concept of life.

Furthermore, (D1) seems to be inconsistent with certain empirical facts. One fact concerns suspended animation. Freezing, drying and certain other procedures may be used to arrest the life functions of formerly living entities. Viruses, bacteria and other micro-organisms are placed in suspended animation in laboratories as a matter of course. Sperm, eggs and blastulas of horses, cows and even human beings may be held in this state for months or years. Since all the life functions of such entities have been suspended, it seems that they have ceased to live. But since they can return to life again later, it seems that they have not died. (D1) therefore fails, since it implies that when such organisms go into suspended animation, they die.

In light of this difficulty with suspended animation, it might appear that it would be better to define death not as the mere cessation of life, but as the *permanent* cessation of life:

(D3) x dies at $t =_{df.} x$ ceases permanently to be alive at t.

If an organism goes into suspended animation but will later return to life, (D3) implies that it has not died as its loss of life was not permanent. Thus, (D3) seems to be an improvement over (D1).

Nevertheless, (D3) is still problematic. Suppose two similar organisms go into suspended animation at some time. Suppose one is later brought back to life, whereas the other is not. Then during the period when both were in suspended animation, the first was not dead (since it had not *permanently* ceased to live) but the second was already dead (since it had *permanently* ceased to be alive). This may seem odd, since the two organisms might have been cell-for-cell duplicates during the period of suspended animation, yet according to (D3) one was already dead and the other was not. This shows that (D3) conflicts with the intuitively plausible notion that the life and death of an organism depends upon the intrinsic character of that organism. Thus none of the traditional analyses of the concept of death is definitively correct. The fundamental question about death remains unanswered: we do not know precisely what death is.

4 The mystery of death

A recurrent theme about death in popular thought (as well as in some philosophical circles) is the idea that death is mysterious. As we have seen, it is difficult to formulate a satisfactory philosophical analysis of the concept of death. If it is impossible to analyse the concept of death, then it is impossible to explain precisely what we mean when we say that something dies. It might be said therefore that, in virtue of this fact, death is mysterious. Of course, death is not *distinctively* mysterious - all other unanalysable concepts are equally mysterious in this way.

Yet it is widely thought that there is a special mystery about death. Some seem to take the mystery to be that we cannot know or even conceive of what being dead will be like. This might be thought to follow from the fact that most of us who are living have no recollection of ever having been dead, and thus we lack first-hand experience of what death is like. Furthermore, since there is considerable doubt about the veracity of the testimony of those few who claim to recall having been dead, none of us has a reliable second-hand report of what death is like.

A deeper reason for thinking death difficult to imagine becomes evident if we suppose that death is an ‘experiential blank’ - that is, if we suppose that the dead have absolutely no experiences. It has been claimed that being dead is impossible to conceptualize precisely because being dead is like this. However, while it must be admitted that it is quite difficult to form any clear conception of what an experiential blank would feel like, this may be a bogus problem. Perhaps it is difficult to imagine this feeling not because it is mysterious or hidden, but rather because there is no such feeling. If the dead have no experiences, then it is no wonder and no mystery that we cannot imagine what the experiences of the dead feel like.

5 The evil of death

If we cease to have experiences at death then we cannot experience pain or any other sort of misfortune while dead. How then can death harm us? And if death cannot harm us, how can it be reasonable for us to fear death? Lucretius claimed that it would be more reasonable for us to view death with the same calm indifference with which we view the infinite stretch of time prior to our creation. These are ancient questions: they were discussed by Plato and by Epicurus and his followers, just as they are still discussed today (see Plato §§7, 13; Epicurus §2).

Dualists who believe that our souls continue to live after our bodies die have an easy reply to these questions. They can say that we do not cease to have experiences at death. If we go to hell, we will suffer eternal torment. Thus, death can harm us and (if we have been bad) it is quite reasonable for us to fear death. Our deaths will mark the beginning of the worst and longest period of misery we will ever experience.

The questions about the evil of death are more puzzling for materialists and others who accept the notion that the dead cannot experience pains or other misfortunes. How can such a person explain the evil of death? Some, such as Thomas Nagel, reject the principle that we cannot be harmed by something that we do not experience. They cite the harms of deprivation: suppose a person suffers a brain injury and is reduced to the mental state of a contented infant - they may experience no pain, and may not be aware of any misfortune, yet they have been seriously harmed simply by the deprivation of their mental capacities. According to a more extreme view, a person may be harmed by falling into nonexistence. Consider a girl who dies painlessly in her youth. Suppose that if she had

lived, she would have been quite happy. Her death therefore seems to deprive her of a lifetime of happiness. Some (for example, McMahan or Feldman) see this as a grave harm - though of course a harm of which the victim has no conscious experience. These philosophers claim that it may be reasonable for us to view death as a great evil - even if we will have no experiences while dead. Perhaps the fear of death is not entirely irrational.

6 The survival of death

For a variety of reasons, many are deeply troubled by the question of whether we will survive death. The question is open to several interpretations. Different interpretations arise from different conceptions of the metaphysics of persons, and from different conceptions of death and survival.

Materialists of one traditional sort maintain that people are just physical objects - their own bodies. On this view, there are no souls. People have psychological properties simply because their brains are functioning properly. A materialist of this sort might take the question about survival to be ‘will I (= my body) continue to exist after I die?’. On this interpretation, the person is taken to be the human body, the survival of which is taken to be continued existence. If we interpret the question in this way, the answer is fairly obvious. In the vast majority of cases the human body does continue to exist for at least a few months after it dies. However, since the brain is no longer functioning, it presumably has no experiences. It is difficult to understand how anyone could take this sort of survival to be of any value to the deceased.

Such a materialist might reinterpret the question to mean ‘will I continue to *live* after I die?’. Almost certainly, the answer to this question must be no. If you are just your body, and your body becomes dead and ceases forever to live when it dies, then you become dead and cease forever to live when you die.

Dualists maintain that each person has both a body and a soul. In classical forms of dualism, the soul is taken to be a non-physical object - not made of atoms or molecules. During life, the soul and body are intimately associated. Some would say that during life the soul ‘animates’ the body. Dualists of one tradition take each person to be a unified complex of body and soul. Descartes sometimes seems to endorse this view of persons (‘ I am not lodged in my body merely as a pilot in a ship, but so intimately conjoined, and as it were intermingled with it, that with it I form a unitary whole’ - *Meditations* VI (1958): 239). It would be natural for such a dualist to adopt the Platonic conception and take death to be the dissolution of the soul-body compound. For such a philosopher, the question about survival may be put thus: ‘Will I (= this complex of body and soul) continue to exist after I am dissolved by death and my parts have gone their separate ways?’. Once we have accepted the metaphysical assumptions of this sort of dualism, the answer to this question seems to be no. If the person is the complex of body and soul, and the complex is destroyed by death, then the person is destroyed by death. Though the parts may continue to exist, the compound itself must cease to exist and to live at death (see Descartes, R. §8) .

Dualists of another tradition take persons to be embodied souls. On this view, each living person is a soul that happens to be attached to a body. Descartes seems in other passages to endorse this view of persons (‘ I have a body with which I am very closely conjoined, yet…I am truly distinct from my body, and can exist without it’ - *Meditations* VI (1958): 239). A philosopher who accepts this metaphysical conception of persons might understand the question about survival in this way: ‘Will I (= my soul) continue to have experiences after my body has died?’. Although some have denied it, the correct answer to this question is conceivably yes, and it is somewhat easier to understand why someone who accepts this metaphysical conception of persons might be interested in this sort of survival.

It is interesting to note that on this second dualistic conception, it is not quite clear that *people* actually die. Of course, *human bodies* die. However, on the view in question, no person is a human body. Each living person is just a soul - albeit a soul that happens to be ensconced in a mortal body. That which continues to live after the death of the body is a thing that does not die - the soul. That which dies - the body - typically deteriorates and eventually goes out of existence after death (see Dualism §1).

7 Immortality

We might think that the concept of immortality is the concept of never dying. However, this would be slightly misleading since it would imply that non-biological objects such as rocks and bricks, atoms and planets, numbers and properties, are all immortal: since they never live, they never die. It would also be misleading to suppose that

the concept of immortality is the concept of living at some time but never dying, since this would also have odd implications. Consider a living thing that goes into eternal suspended animation. It never dies, but this sort of immortality is hardly better than death. It is better, therefore, to take the concept of immortality to be the concept of living forever. This seems more interesting, and is probably closer to the concept that has been discussed.

Some say that eternal life would be a great blessing - something of unsurpassable value. Perhaps they reason as follows: life is good; more of a good thing is always better than less; therefore eternal life is exceedingly good. But others (most notably Bernard Williams) have argued that eternal life could not possibly be desirable. Williams considers several possible ‘models’ of eternal life. On one, a person (identified as ‘E.M.’) remains eternally at the same biological age (in his example, the age is forty-two). Williams claims that after a few hundred years, this person would inevitably become bored with life. The boredom is inevitable, he insists, in virtue of the fact that ‘everything that could happen and make sense to one particular human being of 42 had already happened to her’ (1973: 90).

On another model we imagine that E.M. does not remain at a constant biological age of forty-two, and does not retain a certain character. Rather, we imagine that E.M. lives out an endless succession of different lives, each with a new character and personality. In this way, E.M. avoids the tedium of the first model. Williams suggests that this is not a model on which a single person lives forever. Rather, it is a model on which a series of distinct persons live. Thus, it has no bearing on the question of the desirability of eternal life.

It could be argued, however, that Williams has neglected certain important possibilities. One is the possibility that there are activities whose pleasure does not decrease with repetition. Another is that people may grow and change gradually over time, and thereby come to have new interests without losing their identities as individuals. Such growth might make it possible for a single individual to live forever without falling into the tedium that might result from steadfast pursuit of just one interest over an endless stretch of time.

8 Death and the meaning of life

A number of thinkers have suggested that there is some important connection between death and ‘the meaning of life’. A person who thinks that death is not followed by any sort of afterlife may think that death makes life meaningless. Schopenhauer sometimes seems to have expressed this view (see Schopenhauer, A. §6). Others who believe in God and immortality may see it this way: God placed us here on earth in order that we may either sin or achieve our salvation. If we sin, we are punished with eternal damnation. If we achieve salvation, we are rewarded with eternal bliss. A person who accepts this picture might say that if there were no God and no afterlife in which to receive reward or punishment, then life would be (to quote Shakespeare) ‘a tale told by an idiot, full of sound and fury, signifying nothing’. In other words, if there were no God and no afterlife, our lives would not be components of a larger and purposeful scheme - we would live for a while and then simply die. For many, if it were like this, life would be meaningless. Those who believe in an afterlife may take comfort in thoughts of this afterlife, and think that its existence serves to make ordinary life here on earth meaningful.

Yet it appears that sense can be made of the idea that life is meaningful even if it ends in death. If people have worthwhile goals and exert themselves to achieve these goals, taking some pleasure in both the exertion and the achievement, then their lives may be said to be meaningful - at least in what Paul Edwards calls ‘the terrestrial sense’. Death, of course, may bring an end to such meaningfulness, but the fact that they will someday die seems not to be able to rob people’s lives of this sort of meaningfulness while they are alive.

According to an even more extreme view, life is made *more* meaningful by the recognition that it will end with death. According to this view, we gain a deeper appreciation for the common satisfactions of our everyday experience when we fully realize that someday we will die, and will then have nothing at all.

Deconstruction

Although the term is often used interchangeably (and loosely) alongside others like 'post-structuralism' and 'postmodernism', deconstruction differs from these other movements. Unlike post-structuralism, its sources lie squarely within the tradition of Western philosophical debate about truth, knowledge, logic, language and representation. Where post-structuralism follows the linguist Saussure - or its own version of Saussure - in espousing a radically conventionalist (hence sceptical and relativist) approach to these issues, deconstruction pursues a more complex and critical path, examining the texts of philosophy with an eye to their various blindspots and contradictions. Where postmodernism blithely declares an end to the typecast 'Enlightenment' or 'modernist' project of truth-seeking rational enquiry, deconstruction preserves the critical spirit of Enlightenment thought while questioning its more dogmatic or complacent habits of belief. It does so primarily through the close reading of philosophical and other texts and by drawing attention to the moments of 'aporia' (unresolved tension or conflict) that tend to be ignored by mainstream exegetes. Yet this is not to say (as its detractors often do) that deconstruction is a kind of all-licensing textualist 'freeplay' which abandons every last standard of interpretive fidelity, rigour or truth. At any rate it is a charge that finds no warrant in the writings of those - Jacques Derrida and Paul de Man chief among them - whose work is discussed below.

1 Is there a logic of deconstruction?

What is 'deconstruction' and what does it do? There is a problem here in that Derrida often goes out of his way to disown any summary treatment of the topic or any attempt to define (and so delimit) deconstruction in 'adequate' conceptual terms. Nevertheless one can offer at least some attempt at a working definition. What typically occurs in a deconstructive reading is that the text in question is shown to harbour contradictory logics which are standardly ignored - or concealed from view - on other, more orthodox accounts. Very often it is a matter of locating certain clearly-marked binary oppositions (as for instance between nature and culture, speech and writing, concept and metaphor, or philosophy and literature) and showing that their order of priority is by no means as stable or secure as the text seeks to maintain. That is to say, there is a counter-logic at work whereby those distinctions can be shown to break down, or to generate a reading markedly at odds with the author's overt intent. Not that intention is simply ruled out as irrelevant for the purposes of a deconstructive reading. On the contrary, it offers an 'indispensable guardrail' (Derrida [1967b] 1975: 158) which saves interpretation from running wild in endless subtleties of its own ingenious devising. However, this leaves open the possibility that texts may mean something other - and more - than is allowed for by any straightforward appeal to the warrant of authorial intention.

Thus in each of the above-mentioned cases one term (the first) is conventionally assigned a positive or superior value while the other is construed - by author and mainstream interpreters alike - as self-evidently standing in a dependent, derivative or supplementary relation to it. For Rousseau, nature both precedes culture and represents a better, more authentic way of life, while writing is regarded as a bad 'supplement' to speech, one that involves all manner of corrupting artifice and which infects the very sources of spontaneous 'natural' expression. Yet he cannot describe that idealized 'state of nature' except in terms that perforce acknowledge the *impossibility* of any such state having ever existed. For there is clearly a logical or conceptual problem about an argument that sets up this rigid opposition between nature and culture, but which then proceeds to identify the best (that is, the most primitive, least 'civilized') cultures with an early stage of social evolution that would somehow *not yet* have embarked upon the path to civilization and ruin. The case with speech and writing is somewhat more complex but can be stated along much the same lines (see Rousseau, J. §2).

For Rousseau, speech - in its 'natural' condition - is a mode of utterance that expresses sentiments so directly (with so little room for civilized pretence) that it allows human beings to communicate face-to-face without any need for the kinds of elaborate convention that characterize other, more articulate forms of linguistic exchange. What is bad about writing is precisely its dependence on a graphic notation which involves such artifice as the very condition of its possibility, and which thus stands at the furthest remove from the passional origins of speech. However this argument fails to take account of the conventional character of *all* language, spoken and written alike; that is to say, the extent to which speech partakes of various signifying systems (phonetic, semantic, syntactic and so on) in the absence of which it would simply not qualify as language. Furthermore it is just this reliance on conventions -

a matter of structural necessity - that Rousseau has to recognize (against his own wishes) as an intrinsic condition of language-in-general. For it would then be the case that writing (not speech) might offer the best model for explaining those constitutive features of language - its structural properties, conventional character, capacity to signify in various contexts irrespective of self-present utterer's intentions, and so forth - which necessarily pertain to *all* language, whether written or spoken (Derrida 1989).

There is a parallel here with Wittgenstein's argument against the possibility of a private language, that is to say, his contention that any such 'language' would not in fact constitute a language since it would lack the criteria for shared understanding and hence be wholly unintelligible even to its solitary user (see Private language argument; Wittgenstein, L.). What is distinctive about Derrida's approach to such issues is also what sets deconstruction apart from most work in the 'other' (analytic or Anglo-American) tradition. That is, he treats them as issues specific to the reading of certain problematical passages in certain texts, passages whose overt or manifest sense is shown to be at odds with the structural logic that governs the argument as a whole. Hence Derrida's claim with regard to Rousseau that 'his declared intention is not annulled by this but rather *inscribed* within a system which it no longer dominates' (Derrida [1967b] 1975: 243). However this emphasis on textual close-reading goes along with a keen analytical grasp of the philosophic issues involved and should not, therefore, be taken as evidence that Derrida is practising literary criticism (or a mode of 'merely' rhetorical exegesis) under the guise of linguistic philosophy. Rather he argues from the *conditions of possibility* for raising such questions about meaning, context, authorial intention and so forth, questions that clearly point beyond the sphere of localized interpretative insight or thematic commentary. Thus he is not so much concerned with particular instances of paradox, aporia or self-contradiction in Rousseau's texts. What chiefly engages Derrida's interest is that pervasive 'logic of supplementarity' whereby the second (supposedly inferior or derivative) term in each pair turns out to be always already presupposed in any definition of the first (supposedly original and self-sufficient) term. This logic may resist formalized statement through its complexities of modal structure - which Derrida brings out to striking effect in his reading of Rousseau - and its apparent suspension of classical axioms like bivalence or non-contradiction. But this should hardly place his work beyond the pale for philosophers with a knowledge of developments in recent post-classical (for example, intuitionist or many-valued) logic.

2 Paul de Man and 'aesthetic ideology'

Paul De Man is another thinker whose writing occupies the currently contested zone between philosophy and literary theory. In de Man's case also, the suspicion is often voiced that his practice of minute close-reading - especially when applied to philosophic texts - must go along with a lack of genuine analytic rigour or merely a desire to make trouble by inventing all manner of pseudo-problems. I should not wish to claim that this characterization is entirely wide of the mark, at least as regards de Man's more tortuous attempts to outdo Nietzsche in deconstructing all the concepts and categories of logic, epistemology, causal explanation and other 'metaphysical' notions (de Man 1979). All too often these claims have been taken on trust or treated as a deconstructive *fait accompli* by literary theorists keen to upstage their colleagues in philosophy or the natural sciences. At its best, however, de Man's work cannot be dismissed as simply a product of the turf-battle between rival academic disciplines. In late essays like 'The Epistemology of Metaphor' (1978) on Locke, Condillac and Kant, and 'Pascal's Allegory of Persuasion' (1981) on the relation between suasive or performative language and the language of logical proof-procedures, his thought exhibits an exceptional degree of analytic acuity and rigour. Certainly he is far from advancing the sorts of blanket 'textualist' claim - such as 'all concepts are metaphors', 'all philosophy is a kind of literature', 'all talk of "truth" is just a species of rhetorical imposture', and so forth - that are often attributed to him (and to Derrida) by disciples and opponents alike.

Above all, de Man insists that textual exegesis in the deconstructive mode can at times produce readings sharply at odds with established or mainstream critical opinion. This produces an extreme - some would say perverse - attentiveness to just those kinds of aberrant textual detail (tropological swerves, displacements, substitutions or elisions) which complicate the reading-process beyond any notion of straightforward fidelity to the author's presumed intent. Of course this description might also apply to that mode of 'rational reconstruction' by which some philosophers have lately seen fit to treat the texts of past thinkers with a view to their own, mainly analytic concerns. However it is the aim of this approach to discover some viable (constructive) solution to problems whose importance is taken to justify the strong-revisionist line. For de Man, conversely, it is the purpose of a deconstructive reading to respect the very letter of the text even where this leads to a stage of aporetic deadlock

where the text turns out to contest or subvert its own statements of intent.

Hence his insistence on the stubborn *literality* of deconstruction, that is to say, its power to hold out against the seductive ('eudaimonic') appeal of other, more compliant and therefore - he would argue - less rigorous modes of understanding. For de Man much depends on the way that we read certain passages in the work of philosophers and literary theorists who have reflected - in a more or less self-conscious or critical mode - on these issues of language, knowledge and representation. What he often discovers is an alternating rhythm of co-implicated 'blindness' and 'insight', a rhythm characterized by moments of apparent naïvety (for example, with regard to the supposed organic or consubstantial relation between language and nature) which none the less exist in close proximity to moments of un-self-deceiving rigour (de Man 1983). His aim is to expose the workings of a deep-laid 'aesthetic ideology' whose effect - so he argues - is chiefly manifest in the discourse of post-Kantian philosophy and literary theory. Most often it results from a confusion between linguistic (especially metaphorical) structures and those forms of phenomenal or sensory perception that characterize our knowledge of natural-world objects and processes. Thus : 'literature is fiction not because it somehow refuses to acknowledge "reality", but because it is not *a priori* certain that language functions according to principles which are those, or which are *like* those, of the phenomenal world' (de Man 1986: 11). To suppose otherwise is to fall into a way of thinking that can all too easily be co-opted for the purposes of ideological mystification.

Such is, for instance, the Cratylist delusion - revived by Romantic poet-philosophers like Schiller and Coleridge - according to which it is possible for language (especially the language of symbol and metaphor) to achieve a condition of organic form beyond all the Kantian antinomies of subject and object, mind and nature, or intuitive and conceptual knowledge. Aesthetic ideology can thus be seen as the source of some far-reaching errors, among them - most crucially for de Man - the idea that particular (national) languages and cultures can likewise manifest the kind of predestined, organic development and growth that grants them an inherent superiority over other, more fractured or dissociated forms of cultural-linguistic expression. De Man's notorious wartime journalism, published in Nazi-occupied Belgium, often attributed just such a natural, predestined eminence to German thought and culture. It seems plausible to claim that his later writings were concerned in various ways to challenge or resist what he subsequently saw as the seductive power of an aesthetic creed with large implications for our thinking about issues of culture, politics and moral responsibility. Thus: 'what we call ideology is precisely the confusion of linguistic with natural reality, of reference with phenomenalism'. And again, more pointedly, those who charge deconstruction with a culpable indifference to issues of history and politics 'are merely stating their fear at having their own ideological mystifications exposed by the tool they are trying to discredit. They are, in short, very poor readers of Marx's *German Ideology*' (de Man 1986: 11).

3 Some analytic bearings

Gilbert Ryle lost patience with the so-called 'psychologism' of Husserl, despite having previously published some detailed and constructive (albeit critical) studies of his work (Ryle 1971 - see Ryle, G. §1) . So it was - or so the story is often told - that a rift emerged between phenomenology (along with various derivative 'continental' schools of thought) and later developments in the Anglo-American analytic tradition. This view fitted in with the received idea - initiated by Russell and Frege, and erected into a full-scale programme by logical empiricists like Rudolf Carnap - that philosophy should work to clear away those errors and confusions of natural language that could best be revealed by analysis in the formal or logico-semantic mode (see Analytical philosophy §2). It would also help to resist the kinds of metaphysical bewitchment by language to be seen at their worst (so Carnap thought) in Heidegger's obscurantist appeal to the primordial wisdom supposedly enshrined in Greek and German etymology. Derrida's work has indeed been much influenced by Heidegger, especially as regards its questioning of those various deep-laid 'logocentric' priorities and values whose presence in the Western philosophical tradition is a constant theme of his writing, early and late. However he has also criticicized some aspects of Heidegger's thought, among them precisely the harking-back to a lost originary plenitude of Being (Derrida 1967b). For it is here that Heidegger himself falls prey to a potent irrationalist mystique, an appeal to language - or to certain privileged *national* languages and cultures - as the source of a wisdom supposedly concealed throughout the history of so-called 'Western metaphysics' (see Heidegger, M. §6).

In de Man's work also, Heidegger figures as a prime example of that alternating pattern of 'blindness' and 'insight' which in turn can enable the reader to attain a less prejudiced (if never fully adequate, transparent or

demystified) level of understanding (de Man 1983). Such arguments will scarcely be convincing to those for whom ‘deconstruction’ is pretty much synonymous with the obscurantist ‘jargon of authenticity’ that Heidegger promoted and that Derrida has supplied with its latest fashionable twist. However this notion cannot stand up to the sort of close reading which Derrida brings to his commentary on Heidegger and others, and which his own texts properly require on the part of responsible critics. Here again what has most often got in its way is the fixed preconception - handed down from the logical empiricists - that analytic (that is, genuine or serious) thought should have no truck with such extravagant forms of ‘continental’ pseudo-philosophy.

If the prospects look fair for a mending of this rift, then one clear sign is the current reappraisal (by Michael Dummett (1993) among others) of the strong continuities that exist within and between these two lines of descent. Another is the willingness of some commentators to look again, for example, at Derrida’s reading of J.L. Austin - the target of a well-known hostile response by John Searle (1977) - and to discover not only points of genuine philosophical interest but also a certain affinity between the thought of Austin and Derrida (Austin 1961, Derrida 1989). This emerges, for instance, in their shared alertness to the ways that language (so-called ‘ordinary’ language) can prove more complex and resistant to codification than anything allowed for by speech-act theory in its systematized form. If ‘undecidability’ is in question here - as so often in Derrida’s work - then it is the upshot of a reading closely attentive to the detail and the logic of Austin’s arguments.

Dedekind, Julius Wilhelm Richard (1831-1916)

Dedekind is known chiefly, among philosophers, for contributions to the foundations of the arithmetic of the real and the natural numbers. These made available for the first time a systematic and explicit way, starting from very general notions (which Dedekind himself regarded as belonging to logic), to ground the differential and integral calculus without appeal to geometric 'intuition'. This work also forms a pioneering contribution to set theory (further advanced in Dedekind's correspondence with Georg Cantor) and to the general notion of a 'mathematical structure'.

Dedekind's foundational work had a close connection with his advancement of substantive mathematical knowledge, particularly in the theories of algebraic numbers and algebraic functions. His achievements in these fields make him one of the greatest mathematicians of the nineteenth century.

1 Career

Richard Dedekind was born in Braunschweig, Germany. In 1848 he entered the Collegium Carolinum in that city to study 'mathematics and science', but it was for mathematics that he had already decided. In 1850 he matriculated at the University of Göttingen, and two years later received his doctorate, under the sponsorship of the great C.F. Gauss. In 1854 he 'habilitated' (qualified as a private lecturer) at Göttingen, a few weeks after Bernhard Riemann, who had been a fellow student and who was one of the two greatest influences upon Dedekind's mathematical - and philosophical - career. The second was J.P.G. Lejeune Dirichlet, who succeeded Gauss on his death in 1855. On Dedekind's later testimony, Dirichlet had 'inaugurated a new era for the study of mathematics at Göttingen', and had 'made a new man' of him.

In external details, the story of Dedekind's career is brief: he became a professor at the Polytechnic Institute of Zurich in 1858, then, in 1862, accepted a professorship at the Collegium Carolinum (itself by then a Technical Institute). This position he held until his retirement in 1894, having several times declined offers of university appointments (preferring to remain in his home town and near his ancestral family). After formally retiring he continued to offer occasional courses of lectures until shortly before his death.

Dedekind's style of thought in general was to ponder slowly over the subjects that engaged him; he tended not to publish until he had brought a piece of work to a degree of classic perfection and could display for his readers the heart of the matter with a maximum of clarity. (A word Dedekind uses to characterize this quality he valued in mathematical exposition is 'quietness'. The motto of his work might well have been that explicitly invoked by Gauss: *pauca sed matura* (few, but ripe).)

2 Algebraic numbers and algebraic functions; new conception of mathematical 'objects'

A considerable part of Dedekind's energy during the early years of his career was devoted to the posthumous publication of works by his friends: Dirichlet's lectures on number theory; then Riemann's papers, both published and unpublished.

It was in the elaboration of themes arising from Dirichlet's number-theoretic lectures that Dedekind found the central theme of his own great contributions to mathematics - in the first place, a very far-reaching generalization (and clearer grounding) of the then new theory of algebraic numbers. Dedekind's major publication on this subject took the modest form of a supplement, among a whole series of supplements designed to clarify points arising from the main text, in his edition of the Dirichlet lectures. This work first appeared in the second edition (1871) as 'Über die Komposition der binären quadratischen Formen' ('On the Composition of Binary Quadratic Forms'). It was revised in subsequent editions (1879, 1894), appearing as 'Über die Theorie der ganzen algebraischen Zahlen' ('On the Theory of Integral Algebraic Numbers').

Characteristic of this work from the first was the introduction of a series of notions that have come to form the basis of modern algebra - among them, those of 'field', 'module', 'ideal' (and 'algebraic integer' itself) - on the basis of what we would now describe as structural axiomatic characterizations: thus, for instance, Dedekind defines not only a particular field, but the conditions to be satisfied for any system to be a field. Thus Dedekind effected a move towards regarding mathematics itself as concerned with species of structure explicitly

characterized, rather than with particular kinds of ‘objects’, grasped by ‘intuition’. (In this one may see the influence of Riemann, whose characterization of geometry was quite the same.) It was also characteristic that Dedekind made extensive use of sets (‘systems’ in his terminology) as ‘mathematical objects’ on which operations might be performed; and that he introduced as fundamental the consideration of mappings, both within and between particular structures.

The generality of Dedekind’s formulations in this work opened the way for another significant development: his establishment (in collaboration with Heinrich Weber) of a rigorous foundation for the theory, initiated by Riemann, of algebraic functions of one variable (‘compact Riemann surfaces’), bringing to light a deep algebraic analogy between this theory and that of algebraic integers. The resulting paper (1882) has become a cornerstone of twentieth-century algebraic geometry.

3 Real and natural numbers; their basis in logic

Dedekind’s theory of real numbers and continuity, published in 1872, was motivated, he tells us, by his first obligation to teach the differential calculus (in 1858), and his dissatisfaction with the ‘geometrical’ reasoning upon which one traditionally relied. Beginning from the system of rational numbers, Dedekind remarks that this ordered system contains what we may call ‘gaps’, in the following sense: there exist certain splittings of the system into two non-empty, exhaustive parts, with each element of the one less than each element of the other, such that the ‘lower’ part contains no greatest element and the ‘upper’ part no least (for example, negative numbers and those positive numbers with squares less than 2, on the one hand; and positive numbers with squares greater than 2, on the other). He calls a system *continuous* if such gaps never occur; remarks that, whereas ordinary geometry tacitly assumes continuity for the system of points on a line, this is by no means a conceptually necessary property of space - it should rather be postulated explicitly when desired; and shows how, for a non-continuous system such as that of the rational numbers, one can construct a continuous extension by introducing a new element for each ‘gap’, so placed in the ordering as to ‘fill’ the gap. Most crucially, Dedekind (1) proves that the new system so constructed automatically fulfils the requirement of continuity, and (2) defines, in the numerical case, arithmetic operations for the new (‘irrational’) numbers (and between them and the rationals), and demonstrates that all the properties needed for traditional mathematics hold.

Dedekind’s work on the natural numbers was done between 1872 and 1878, but published only in 1888. It is based on the definition of a ‘simply infinite system’: a set *N*, with a one-to-one mapping ϕ of *N* into itself, and an element (called ‘1’) in *N* that is not taken on as a value by ϕ, such that every element in *N* belongs to what Dedekind calls the ‘chain’ of 1, that is, the intersection of all sets that contain 1 and are ‘closed under ϕ’ - that is, contain, together with any element *x*, its image $\phi(x)$. Dedekind shows how this definition justifies the principle of mathematical induction for any simply infinite system (see Logicism §3), and how it also justifies the powerful technique of recursive definition. According to Dedekind, ‘the system of the natural numbers’ is just any simply infinite system, whose elements are regarded without respect to anything but their position in that system. This characterization (from which Giuseppe Peano directly borrowed his axioms for arithmetic) has been crucial for subsequent foundational work in mathematics (see Arithmetic, philosophical issues in §4).

Besides his published work, Dedekind made significant contributions, in his correspondence with Georg Cantor (1937), to set theory and to point-set topology, which the latter was then developing.

HOWARD STEIN

List of Works

Dedekind, R. (1930-2) *Gesammelte mathematische Werke (Collected Mathematical Works)*, ed. R. Fricke, E. Noether and Ö. Ore, Braunschweig: Vieweg, 3 vols.(Dedekind’s collected works. Volume 3 reproduces several of the works given here.)

Dedekind, R. (1871) ‘Über die Komposition der binären quadratischen Formen’ (‘On the Composition of Binary Quadratic Forms’), in P.G. Lejeune Dirichlet, *Vorlesungen über Zahlentheorie (Lectures on Number Theory)*, ed. R. Dedekind, Braunschweig: Vieweg, 2nd edn, supplement 10; passages significantly altered in subsequent edns are repr. in Dedekind (1932), vol. 3, 223-61.(The first version of Dedekind’s fundamental work on the theory of algebraic integers. Later versions were published in 1879 and 1894 (see below).)

Dedekind, R. (1872) *Stetigkeit und Irrationalzahlen*, repr. in Dedekind (1932), vol. 3, 315-34; trans. W.W. Beman, ‘Continuity and Irrational Numbers’, in *Essays on the Theory of Numbers*, New York: Dover, 1963. (His classic work on the construction of the real numbers and the notion of ‘continuity’ or ‘Dedekind completeness’.)

Dedekind, R. (1879, 1894) ‘Über die Theorie der ganzen algebraischen Zahlen’ (‘On the Theory of Integral Algebraic Numbers’), in P.G. Lejeune Dirichlet, *Vorlesungen über Zahlentheorie (Lectures on Number Theory)*, ed. R. Dedekind, Braunschweig: Vieweg, 3rd and 4th edns, supplement 11; repr. in Dedekind (1932), vol. 3, 1-222, 297-313; 4th edn repr. New York: Chelsea, 1968.(The later versions - each very significantly reworked - of the theory first published in 1871.)

Dedekind, R. and Weber, H. (1882) ‘Theorie der algebraischen Funktionen einer Veränderlichen’ (‘Theory of the Algebraic Functions of One Variable’), *Journal für reine und angewandte Mathematik* 92: 181-290; repr. in Dedekind (1930), vol. 1, 238-349.(A fundamental contribution to algebraic geometry.)

Dedekind, R. (1888) *Was sind und was sollen die Zahlen?*, Braunschweig: Vieweg; repr. in Dedekind (1932), vol. 3, 335-90; trans. W.W. Beman, ‘The Nature and Meaning of Numbers’, in *Essays on the Theory of Numbers*, New York: Dover, 1963; trans. *What are Numbers and What Should They Be?*, Orono, ME: Research Institute for Mathematics, 1995.(His classic work on the foundations of the theory of the natural numbers. Characterized by Dedekind’s usual clarity, but a little laborious in its working-out of basic set-theoretic relations. The title is somewhat misconstrued in translation as it should more properly be rendered as ‘What are Numbers and What are They For?’ or ‘The Nature and Function of Numbers’ - see Stein (1988: 246-7).)

Dedekind, R. (1890) *Letter to H. Keferstein*, trans. H. Wang and S. Bauer-Mengelberg, in J. van Heijenoort (ed.) *From Frege to Gödel: A Source Book in Mathematical Logic, 1879-1931*, Cambridge, MA: Harvard University Press, 1967, 99-103.(A masterly presentation, in a short space, of the basic ideas of Dedekind (1888). A very useful guide for the beginner.)

Dedekind, R. and Cantor, G. (1937) *Briefwechsel Cantor-Dedekind (Cantor-Dedekind Correspondence)*, ed. E. Noether and J. Cavaillès, Paris: Hermann; French trans. in J. Cavaillès, *Philosophie mathématique*, Paris: Hermann, 1962.(Includes most of the correspondence of Dedekind and Georg Cantor. The surviving portion of the correspondence not included in this collection is published in Dugac (1976).)

Deductive closure principle

It seems that one can expand one's body of knowledge by making deductive inferences from propositions one knows. The 'deductive closure principle' captures this idea: if S knows that P, and S correctly deduces Q from P, then S knows that Q. A closely related principle is that knowledge is closed under known logical implication: if S knows that P and S knows that P logically implies Q, then S knows that Q. These principles, if they hold, are guaranteed by general features of the concept of knowledge. They would form part of a logic of knowledge.

An influential argument for scepticism about knowledge of the external world employs the deductive closure principle. The sceptic begins by sketching a logically possible hypothesis, or counter-possibility (for example, that one is a brain in a vat, with computer-induced sense experience) which is logically incompatible with various things one claims to know (such as that one has hands). The proposition that one has hands logically implies the falsity of the sceptical hypothesis. Supposing that one is aware of this implication, the deductive closure principle yields the consequence that if one knows that one has hands, then one knows that one is not a brain in a vat. The sceptic argues that one does not know this: if one were in a vat, then one would have just the sensory evidence one actually has. It follows that one does not *know that one has hands. Some philosophers have sought to block this argument by denying the deductive closure principle.*

1 Closure principles

According to the 'deductive closure principle', if S knows that *P*, and S correctly deduces *Q* from *P*, then S knows that *Q* (call this principle 'Closure'). The set *X* of propositions which one knows is not closed (in the mathematical sense) under logical implication *simpliciter*. This is because there are countless propositions which are logical consequences of what one knows which one does not recognize as such. Since one does not believe these logically implied propositions, one does not know them, and so they are not members of *X*. A similar point holds for the closure principle for known logical implication: it seems possible for one to know that *P*, know that *P* implies *Q*, and yet fail to deduce *Q*. According to Closure, those logical consequences which one deduces from what one knows are members of *X*. Such deduced consequences meet two of the conditions for knowledge: they are true (since they follow from known, and therefore true, propositions), and they are believed. If these deduced consequences are to be known, as Closure says, then they must satisfy whatever further necessary conditions for knowledge there might be.

Suppose that *having justification for believing that P* is a necessary condition for knowing that *P* (see Knowledge, concept of §2; Justification, epistemic). Then it is plausible to suppose that Closure will hold only if *closure for justification* holds: if S has justification for believing that *P*, and S correctly deduces *Q* from *P*, then S has justification for believing that *Q*. This principle is used in constructing Gettier examples in which one starts with a justified belief of a false proposition (such as that Jones has ten coins in his pocket and will win the race) and deduces a proposition (say, that someone who has ten coins in his pocket will win the race) which just happens to be true. If closure for justification holds, then one will have a justified, true belief that does not amount to knowledge (see Gettier problems).

S may have justification for believing that *P* without actually believing that *P* (for example, S may fail to realize that S's evidence justifies a belief about the identity of the killer). Thus it is plausible to hold that justification is closed under logical implication *simpliciter*: if S has justification for believing propositions which logically imply *Q*, then S has justification for believing that *Q*. This principle is employed in generating the lottery paradox. One holds a ticket in a very large, fair lottery which one justifiably believes will have just one winner. Assume that the very high probability that one's ticket will not win justifies one in believing that one's ticket will not win. Since similar reasoning will apply to every other ticket, one has justification for believing that the first will not win, one has justification for believing that the second will not win, and so on. Given that these propositions logically imply that no ticket will win, the closure principle now under consideration implies that, paradoxically, one has justification for believing that no ticket will win (see Paradoxes, epistemic §1).

2 Justification and relevant alternatives

Fred Dretske (1970) describes a case which appears to be a counterexample to both closure for justification and

Closure itself (assuming that justification is a necessary condition for knowledge). Here we see again that the assessment of Closure depends on one's views about the analysis of the concept of knowledge. At the local zoo, one sees some striped animals in an enclosure marked 'Zebras'. One's evidence justifies a belief that these animals are zebras. However, one's evidence does not count towards their *not* being cleverly disguised mules (since one would have exactly similar evidence were it a hoax). Therefore, one's evidence does not justify one in believing the proposition that these animals are not cleverly disguised mules, even though one recognizes (we will suppose) that that proposition is logically implied by the zebra proposition for which one has justification.

A sceptically minded philosopher might well object that it is far from clear that one's evidence does justify a belief that the animals are zebras. To the extent that one's evidence does not count against the cleverly disguised mule hypothesis, the sceptic would say, it does not count in favour of the zebra hypothesis.

Dretske sketches a general theory of knowledge which bolsters his appeal to brute intuition about the proper analysis of the zebra case (intuition which might beg the question against scepticism). He holds that when S knows that *P* in some particular context, there is a range of *relevant alternatives* (counter-possibilities) to *P* which is a subset of the set of *all* alternatives to *P*. To know that *P*, it is only required that S be able to rule out the relevant alternatives to *P*. On this theory, Closure fails, because there will be situations in which S knows that *P*, knows that *R* is an alternative to *P* (knows that not-*R* is logically implied by *P*), and yet is unable to rule out *R* (fails to know that not-*R*). These are situations in which *R* is an *irrelevant* alternative to *P*.

The main motivation behind the relevant-alternatives theory is to provide a way of blocking the Cartesian sceptical argument. Therefore, we need an account of *relevance* according to which the sceptic's bizarre alternatives to ordinary propositions about the external world turn out to be irrelevant. This will make it possible for one to know that one has hands while lacking knowledge that one is not a disembodied brain in a vat. There is little agreement among relevant-alternative theorists on the analysis of the concept of relevance. One view is that an alternative *R* is relevant with respect to a particular claim to know that *P* if and only if the objective probability of *R* meets some specified level. If there are hoaxing zoos in one's vicinity, then this could render the cleverly disguised mule possibility a relevant alternative in the zebra case. Another view is that alternative relevance is determined by various features of the conversational context in which a knowledge attribution is made (a context which might not include the putative knower). The mentioning of alternatives might be such a contextual feature, so that the brain in a vat alternative can become relevant in a philosophical discussion of knowledge.

It has been argued (Klein 1981) that closure for justification holds even though (as Dretske claims) one's evidence *E* may justify a belief that *P* without justifying a belief of a deduced proposition, such as that one is not in a vat. On this view, even though *E* does not justify one's belief that one is not in a vat, one still has an adequate reason for believing that proposition. This is because *P* itself becomes available as evidence for the deduced proposition, given that *E* justifies one's belief that *P*.

3 Closure and reliabilist theories of knowledge

Let us consider the *reliabilist* approach to the analysis of the concept of knowledge, according to which knowing that *P* is a matter of having a reliably produced true belief that *P*. On many such accounts, the justification condition for knowledge is either analysed as, or replaced by, a reliability condition (see Reliabilism). Whether Closure fails on such an analysis depends on how reliability is conceived. On one conception (Goldman 1976), in order for S's belief that *P* to count as reliably produced, S must be able to discriminate the actual situation in which *P* is true from those *relevant possible situations* in which *P* is false. This is close to the relevant alternatives theory, and Closure will accordingly fail. If a possible situation in which *P* is false and S is envatted is not a relevant one, then S can know that *P* without being able to discriminate the actual situation from the one in which S is envatted. Now consider S's claim to know the logically implied proposition that S is not envatted. A possible situation in which S *is* envatted is plausibly regarded in this case as a relevant alternative possibility. Since, as we assumed, S is unable to discriminate the actual situation from a vat situation, it follows that S does not know that S is not in a vat. Thus Closure fails, since S can know that *P* without knowing that S is not envatted.

Reliability is sometimes conceived as having an explicitly counterfactual dimension. For example, Robert Nozick's (1981) 'tracking' analysis of knowledge contains this counterfactual condition: if *P* were false, then S would not mistakenly believe that *P*. Suppose that S claims to know that S is sitting, on an occasion when S is

sitting in a perfectly normal environment. If S were not sitting, then, presumably, S would be standing, or lying down, or the like. In such a counterfactual circumstance, S would *not* mistakenly believe that S is sitting. So S's claim to know that S is sitting satisfies Nozick's counterfactual condition (as well as the other conditions for knowing, we may suppose). Now consider S's claim to know the logically implied proposition that S is not in a vat. If S *were* in a vat, then, presumably, S *would* mistakenly believe that S is *not* in a vat. So S does not satisfy the counterfactual condition for knowing that S is not in a vat. Thus on the present analysis, S knows that S is sitting but fails to know that S is not a brain in a vat.

According to an alternative counterfactual conception of reliability, whether a belief that *P* is reliably produced does not necessarily depend on what one would believe in counterfactual circumstances in which *P* is false. Instead, we focus on the process which issues in the belief. A belief-forming process will count as reliable just in case the process actually yields a sufficiently high ratio of true beliefs and also would yield the required ratio in counterfactual circumstances similar to one's actual circumstances (which might not include circumstances in which *P* is false). Closure will hold on this version of reliabilism. Suppose that one forms the correct belief that one has hands via an ordinary perceptual process. Then one forms the further belief that one is not disembodied in a vat, via the belief-forming process of deductive inference. This inferential belief issues from a process that is obviously reliable in the sense under consideration. Thus if the original belief issues from a process which is reliable in that sense and therefore amounts to knowledge, then so will the inferential belief.

In the end, we see that even though the denial of the closure principles we have discussed would aid in the refutation of scepticism, whether these principles hold is a controversial matter which depends on the nature of knowledge and justification.

Definition

A definition is a statement, declaration or proposal establishing the meaning of an expression. In virtue of the definition, the expression being defined (the ‘definiendum’) is to acquire the same meaning as the expression in terms of which it is defined (the ‘definiens’). For example, ‘Man is a rational animal’ determines the meaning of the term ‘man’ by making it synonymous with ‘rational animal’. Classical theory maintains that a good definition captures the ‘real nature’ of what is defined: ‘A ‘‘definition’’ is a phrase signifying a thing’s essence’ (Aristotle). Historically, philosophers have come to distinguish these ‘real’ definitions from ‘nominal’ definitions that specify the meaning of a linguistic expression rather than signify the essential nature of an object, ‘making another understand by Words, what Idea, the term defined stands for’ (Locke).

A further distinction can be drawn between contextual or implicit definitions, on the one hand, and explicit definitions, on the other. Often a definition fixes meaning directly and explicitly: for example, the definition of a proper name might well take the form of an explicit identity statement (‘Pegasus = the winged horse’) and a definition of a predicate is usually given (or can be re-cast) in the form of an equivalence (‘For every x: x is a man if and only if x is a rational animal’). But sometimes the meaning of a term is specified in context, by way of the meaning of larger expressions in which the term occurs. A paradigmatic example of this is Bertrand Russell’s analysis of the meaning of the definite article.

1 The role of definitions

A definition is a statement, declaration or proposal (the ‘definiens’) establishing the meaning of an expression (the ‘definiendum’). Explicit definitions can be viewed as providing useful abbreviations for complex expressions. It follows that, strictly speaking, they are theoretically dispensable, in so far as we can always replace the definiendum by the definiens in any context. This was already noted by Whitehead and Russell in *Principia Mathematica*, according to whom definitions are ‘mere typographical conveniences’ ([1910] 1925: 11). However, they also point out that from a more pragmatic point of view, the use of a definition (whether explicit or not) conveys additional information besides the literal meaning of the sentence in which the definiendum occurs.

This can happen in two ways. First, a definition calls attention to the fact that the (complex) concept expressed by the definiens plays an important role in the discourse in which the definiendum is used: for instance, agreeing to mean by ‘prime’ a number that can be divided without remainder only by 1 and itself calls attention to the importance of this notion for number theory. ‘Hence the collection of definitions embodies our choice of subjects and our judgment as to what is most important’ ([1910] 1925: 11-12). Second, a definition may sometimes supply an analysis of an already existing concept that had not previously been made precise. In this case the newly introduced concept shares most or all of the traits of its informal counterpart, although realizing those traits in a more specific and precise manner. It should be observed that in general many competing, equally precise and sometimes formally equivalent analyses of the same informal idea are possible, and the choice among them is then inspired by considerations such as simplicity, elegance and adaptability to the particular context of application.

A related view of definitions was put forward by Carnap (1947), who characterizes certain definitions as ‘rational reconstructions’ of less precise concepts derived from everyday life or earlier stages of scientific development. Such a definition is called an ‘explication’, and the newly defined term the ‘explicatum’; the earlier, less precise concept is referred to as the ‘explicandum’. In giving an explication, one ‘sharpens’ a vague, pre-existing concept, making it precise; or even replaces it with a new, more exact one. In general it is not required that the explicandum have the same meaning as the explicatum. All that is required is some sort of correspondence between the two concepts, in such a way that the latter can be used instead of the former. This task of rational reconstruction is ‘one of the most important…of logical analysis and logical construction’ ([1947] 1956: 7-8).

2 Formal conditions on definability

From a purely formal point of view, a definition given in the context of some theory behaves just like any other axiom of the theory, in that it can be used to infer propositions (theorems). However, as already noted by Whitehead and Russell, a definition should not convey any new information: the theory T' obtained by supplementing some theory T by a definition should, in some sense, be equivalent to T.

It is possible to make this requirement precise by laying down two criteria that a definition should satisfy: eliminability and non-creativity. It appears that these criteria were first formulated by the Polish logician S. Leśniewski (1931), but the presentation given here follows P. Suppes (1957).

In order to explain the two criteria, we will suppose that we are working within a formalized background theory T, that is, a set of axioms expressed in some formal language. In such a language, as is customary, free variables are to be construed as implicitly universally quantified; moreover, T is assumed to be consistent. A definition then is just a sentence ϕ that involves some new symbol not already in T. In particular, ϕ is allowed to occur in inferences from the axioms of T. The two criteria can be formulated as follows. A sentence ϕ introducing a new symbol satisfies the criterion of eliminability if and only if whenever η is a formula in which the new symbol occurs, then there is a formula θ in which the new symbol does not occur and such that $(\eta \leftrightarrow \theta)$ can be inferred from T augmented with ϕ. Similarly, we say that ϕ satisfies the criterion of non-creativity if and only if whenever θ is a sentence not involving the new symbol and such that $\phi \rightarrow \theta$ can be inferred from T, then θ can already be inferred from T; in other words, the introduction of the definition does not make possible the derivation of any new theorems that do not involve the new symbol. (One then says that $T + \phi$ is a 'conservative extension' of *T*.) Notice that the second criterion implies, in particular, that the theory supplemented by the definition be free of contradictions: inconsistency is a strong form of creativity.

Although the two criteria apply to explicit and implicit definitions alike, in the case of explicit definitions it is possible to lay down certain constraints on the syntactic form of the sentence ϕ ensuring that the two criteria are automatically satisfied. For simplicity, we will review these constraints only for the case in which the definiendum is a relation symbol or an individual constant (name), but a similar constraint can be formulated for the definition of function symbols.

A formula ϕ is an acceptable definition of an n-place relation symbol R if and only if ϕ has the form $R(x_1, \ldots, x_n) \leftrightarrow \theta$, where $x_1, \ldots, x_n$ are all distinct variables and θ is a formula all of whose free variables are among $x_1, \ldots, x_n$ and in which R does not occur. The requirement that the variables $x_1, \ldots, x_n$ all be distinct is necessary to ensure that the eliminability criterion is satisfied, as is the further requirement that the definiendum R not be allowed to occur in the definiens; jointly, the two requirements are also sufficient for the satisfaction of the eliminability criterion.

The requirement that the definiens not contain any variables that do not already occur in the definiendum is meant to ensure non-creativity. To see that the constraint expresses a necessary condition, consider, for instance, the definition '$G(x) \leftrightarrow x > y$'. Since free variables are implicitly universally quantified, the definition is equivalent to the conjunction of '$G(x) \rightarrow \forall y(x > y)$' and '$\exists y(x > y) \rightarrow G(x)$'; by transitivity of implication we obtain that if $\exists y(x > y)$ then $\forall y(x > y)$, which, when interpreted as a statement of arithmetic, is false. The definition is therefore creative. (The constraint on variables is also sufficient for non-creativity if and only if the definiendum is not allowed to occur in the definiens.)

The constraint on the explicit definition of individual constants is slightly more complex, due to the existential import of such constants in ordinary logic. Rather than considering definitions in the form of an explicit identity '$c =$ the so-and-so', we will give a constraint using the more general form of an equivalence. A sentence ϕ is an acceptable definition of an individual constant c if and only if ϕ has the form $c = x \leftrightarrow \theta$, where θ is a formula not containing c with x as its only free variable, and such that $\exists! x\theta$ (that is, there is one and only one x such that θ) is derivable from the theory.

3 Contextual definitions

Sometimes it is neither possible nor convenient to give a definition in the explicit form of an equivalence or identity. Indeed, given that formally definitions are just further axioms, any sentence containing a new symbol could be taken to be a candidate for a definition of that symbol. Such definitions are called 'contextual', in that the meaning of the new symbol is specified (at least partially) by giving the meaning of some larger expression in which it occurs; the symbol itself, when occurring in isolation, need not be endowed with any meaning at all. Perhaps the first and most conspicuous example of contextual definition is given by Russell (see, for example, Whitehead and Russell [1910] 1925: 66; but see also Frege1884, 1903), when specifying the meaning of the definite article by giving explicit truth-conditions for sentences in which it occurs. As is well known, Russell

proposes to analyse sentences of the form 'The ϕ is ψ' as the conjunction of the three following sentences in which the definite article no longer occurs: (1) There is at least one ϕ; (2) There is at most one ϕ; and (3) Whatever is a ϕ is a ψ. Other examples are the contextual definition of the membership symbol '$\in$' given by the axioms of set theory, and the usual recursive definition of '$+$' in the context of arithmetic (the latter is given by the conjunction of the two equations $x + 0 = x$ and $x + y' = (x + y)'$, where x' denotes the successor of x).

Of course, in general, one would not expect the criterion of eliminability to be satisfied, for a contextual definition need only tell us how to find an equivalent not involving the new symbol for a restricted class of sentences, namely those in which the definiendum occurs in the context given by the definition. For instance, the usual recursive definition of '$+$' does not tell us how to eliminate this symbol in the context $\forall x \forall y(x + y = y + x)$. But the criterion of non-creativity still applies, along with the weaker requirement that the theory augmented by the definition still be consistent.

As a related question one might consider whether, within the framework of a particular theory, a contextual definition can be replaced by an explicit one. A useful tool in answering this question is a method invented by A. Padoa (1902) and further developed by Tarski (1956: 296-320). The method relies on the fact that if a symbol α is explicitly definable within a given theory T, then any two interpretations on which all sentences of T are true must agree on the interpretation of α. Therefore, in order to show that α is not explicitly definable in T it suffices to exhibit two interpretations of T that assign different values to α.

Padoa's method also has a converse of sorts, which is a deep result about the expressive power of first-order logic. Let us say that a symbol α is 'implicitly definable' in T if any two interpretations of T agree on the value they assign to α. (So implicit definitions are a particular case of contextual definitions.) The proposition that any symbol implicitly definable in T is also explicitly definable is known as Beth's definability theorem (see Beth's theorem and Craig's theorem). This is a powerful theorem, and one of the results of model theory with the most far-reaching philosophical implications.

4 'Circular' definitions

We have seen that one of the constraints on the syntactic form of definitions meant to ensure the satisfaction of the criterion of eliminability is that the definiendum itself not occur in the definiens. That is, the requirement rules out 'circular' definitions. This is in keeping with the idea that a definition, among other things, should also provide a way to determine the extension of the defined term, that is, the set of entities that fall under it. Indeed, a way of determining whether an object x falls in the extension of, say, a predicate P is to ascertain whether x satisfies the definiens of P: if the definiens itself is allowed to have occurrences of P, then it might be impossible to determine whether anything satisfies it without knowing the extension of P. So circularly defined terms would lack a definite criterion of applicability.

However, there are circumstances in which it appears that no non-circular definition is available for a given concept. Consider, for instance, the concept of truth, construed as a predicate of sentences of a given language. If the language in question itself contains the truth-predicate then we can have circularity as follows. Tarski (1944) suggested that for any sentence ϕ, the following equivalence (known as a 'T-biconditional') might be regarded as a *partial* definition of truth: t is true if and only if ϕ, where t is a term denoting ϕ (for instance, t could be obtained by enclosing ϕ in quotes). If ϕ itself contains occurrences of 'is true', the T-biconditional for ϕ exhibits a form of circularity. As is well known, this circularity can lead to paradoxes, as in the case of the so-called liar paradox arising from the consideration of the T-biconditional for the sentence λ: λ is not true. As another example, consider the kind of (harmless) circularity that arises when we are trying to specify a function f by means of the two equations $f(x, 0) = x$ and $f(x, y') = (f(x, y))'$, where as before x' is the successor of x (this is harmless because, as is well known, the two equations above identify a unique function over the natural numbers, namely addition).

A general theory of possibly circular definitions was put forward by A. Gupta and N. Belnap (1993). They regard a definition not as supplying a way to fix the extension of a term, but as providing a 'rule of revision', that is, a way of improving upon hypothetical extensions. Suppose we have a possibly circular definition of a 1-place predicate P, which has the form $P(x) \leftrightarrow \phi(P)$, where the definiendum P occurs in the definiens. This can be viewed as an operation defined over the space of the possible extensions of P (that is, over the set of all subsets of the domain):

given a possible extension E as input the rule of revision returns the value of $\phi(P)$ when P is interpreted as E. In turn, a revision rule can be used to give rise to a revision process, that is, an infinite sequence of possible extensions, defined as follows. We begin with an arbitrary extension E as a 'bootstrapper' or initial guess; we then let E_1 be the result of applying the revision rule to E, E_2 the result of applying the revision rule to E_1, and so on. In this way we obtain an infinite sequence. Say that an extension E' 'coheres' with such a sequence if it contains all items that are eventually in every member of the sequence, that is, all items x such that for some E_n, x is in E_i for every $i \geq n$. We can then extend the sequence into the transfinite by letting E^∞ come after each member of the sequence, where E^∞ is an arbitrary extension that coheres with the sequence, and start applying the revision rule again.

So each revision rule specifies a class of revision processes, each one of which is characterized by a different 'bootstrapper' and different 'guesses' at limit stages. Should a revision process culminate in a fixed point, that is, an extension that is returned unchanged by the revision rule, we have found a 'good' candidate for the extension of P. But it should be noted that this is a by-product of the definition: the meaning of the definition is not given by the extension (which might not exist), but by the pattern of variation exhibited by the various revision processes to which it gives rise.

Definition, Indian concepts of

*Definitions in Indian philosophy are conceived very differently from definitions in Western philosophy. In Western philosophy and logic, it is usual to define a term or a linguistic expression. A definition here consists of a 'definiens', typically a longer expression, statement or proposal, and a 'definiendum', a shorter expression or term whose meaning is established by the definiens. Definitions permit the definiendum to be put in place of the definiens and are thus 'abbreviations' (for example, 'father' is an abbrevation of 'male parent'). In India, definitions in the sense of abbreviations were regularly used in grammar from the earliest times, as in the work of Pāṇini (*c.*800 BC).*

*In Indian philosophy, however, definitions are not conceived of as abbreviations. We may have direct acquaintance with an object; this is one way of knowing it. We may also know an object or many objects through their properties or features; this is another way of knowing them. These properties or features are the modes under which objects are cognized. If we know objects through the properties that belong to all of them and only to them, then the objects are collected together through their properties to form a group. A group is nothing real; it is a way of collecting objects by knowing them under one mode. When we know a group of objects through properties common to all of them and only to them, we may also want to know another set of properties or features which also belongs to all the objects and only to them. The second set of properties is the defining mark (*lakṣaṇa*), or, simply, the definition, of the objects collected together into a group by being known under one mode. The objects themselves are the definienda of the definition. The first set of properties through which the definienda are collected together to form a group is called 'the limiting properties of being the definienda of the definition'. The defining mark, that is, the definition, is not an essential property of the definienda, but is only a property (or set of properties) common to all of them and only them.*

1 General features of definition

There are two stages in the Indian theory of definition: (1) the objects to be defined must all be known under one mode ('the limiting property of being the definienda'); and (2) the definition of those objects must be a property coextensive with the limiting property. The limiting property and the definition cannot be identical, although they must be coextensive. A single object, too, can be defined. Its defining mark, that is, its definition, depends upon the prior act of identifying it. The object's criterion of identity is the limiting property of being the definiendum, which has to be different from the defining mark.

A sentence stating the defining mark of a group of objects is called 'the sentence of definition'. It has some special features which should be noted. A sentence of definition has to be a general sentence applicable to all the definienda. In Indian philosophy, variables are not used; pronouns are used to attain generality. For example a true cognition (not 'a true cognition') is defined as a cognition having *that* as a predicate in a *that*-possessor. For example, if a thing has potness (that is, is a pot), then the cognition that the thing has potness (that it is a pot) is a true cognition. Using the pronoun 'that' twice in the sentence makes it a general sentence. For we may write any property term for 'that'.

As objects belonging to very different ontological categories can be the definienda of a definition, the defining mark may belong to the different kinds of definienda by very different ontological relations. This is a peculiarity of the Indian theory which distinguishes it from the theories of traditional Western logic.

2 Navya-Nyāya theory of definition

Only Navya-Nyāya ('New Logic'), created by Gaōgeśa (*c.*1325) and developed by Raghunātha (*c.*1530), Jagadīśa (*c.*1620), Gadādhara (1604-1709) and later philosophers, has a fully developed theory of definition.

There are two fundamental ways in which the Navya-Nyāya theory of definition differs logically from Western theories, apart from the ontological point of view. First, it differs from Plato's theory in that whereas Plato tries to find out the essence or the universal of, say, justice, in Navya-Nyāya, definitions are properties, not necessarily universals or essences, and may even be individual properties belonging to single individuals.

In Plato, Aristotle and Porphyry, there is a hierarchy of genus and species, and definition is *per genus et*

differentiam. Thus every definition must have at least two components - the generic property and the differentia; the defining property of 'human', for example, is animality-and-rationality. The Navya-Nyāya theory of definition is fundamentally different because the structure of the defining property is not always composite, especially when it is a proper universal in the sense of Nyāya. A universal is an unanalysable property, even though it may be subsumed under a wider universal. No universal is a composite of a generic property and differentia. Thus the defining property of humans is just humanity, even though it is subsumed under the generic property of animality. According to Navya-Nyāya, humanity as a property is as simple as animality and cannot be obtained by adding differentia to the generic property. Analysis of a concept is possible only in the case of composite properties, which are not proper universals. Universals, when not referred to by an expression, are known in and through themselves and not under the mode of some other property, and therefore do not stand in need of analysis; indeed, they cannot be analysed at all. It has been objected that although it is correct to say that what games have in common is their being games, it is not at all enlightening. But enlightenment, if sought by further analysis, is not possible in this case.

3 Navya-Nyāya theory of relations

The second fundamental point of difference between the Navya-Nyāya theory and traditional Western theories of definition stems from the Navya-Nyāya doctrine that a defining property need not be a universal. A proper universal is related to all its instances by one relation, inherence, according to Navya-Nyāya. The defining property is very often a property different from a proper universal and is often related to different types of objects by different types of relations. Navya-Nyāya therefore developed a very elaborate technique of showing how the defining property can be said to be 'common' to objects which very often belong to ontologically different categories. This is done by determining the specific nature of the relation by which the defining property can be said to be 'common to' the different types of objects. This specific relation between the defining property and the different types of objects is very often the sum of the different relations by which the defining property is related to different types of objects. This sum of relations is necessary, for it is by this relation that the defining property can be said to be 'common to' all the different types of objects. As an example of this technique of showing how a defining property is 'common to' all the objects to be defined, we may explain the definition of *being a positive object* (*bhāvatva*). According to Navya-Nyāya, there are six ontological categories of positive reals. There is one proper universal common to the first three categories of positive reals, namely existence (*sattā*), which is the highest universal (*parā jāti*). This universal is related to six categories: (1) substance, (2) quality, (3) motion, (4) universal, 5) ultimate differentia, and (6) inherence (see Nyāya-Vaiśeṣika §§4-5; Ontology in Indian philosophy).

Existence is a property common to the first three categories in the sense of being related to them by inherence. Now, according to Navya-Nyāya, the remaining three categories of objects do not have existence inhering in them. Thus, if existence is to be the defining property of being a positive object it must be related to the last three categories of objects by other relations. Navya-Nyāya shows how existence can be indirectly related to the fourth and fifth categories of objects. Universals and ultimate differentia inhere in, say, substances, in which existence also inheres. In Navya-Nyāya terminology, existence is related to universals (and ultimate differentia) as both inhere in the same object.

Still there is the problem of showing how existence can be related to inherence itself, for inherence is the sixth category of positive reals. Existence cannot inhere in inherence, for according to Navya-Nyāya, existence inheres in only the first three categories of positive reals. According to Navya-Nyāya, existence is related to, is located in, inherence by a self-linking relation which is ontologically inherence itself. There is no need to postulate an ontologically different relation between existence and inherence. Inherence, which is the second term of the relation, also functions as the relation. Thus, although the relation between existence and inherence is not *inherence as inherence*, but only *inherence as a self-linking relation*, still it is inherence which is ontologically the same as this relation.

In Western logic, universal laws are formulated by means of variables. These variables are signs bound by some operators, and also act as place-holders for names of their values. Because of the convention that the same name in to be written at all places where a variable occurs (within the scope of one quantifier, or in the same formula if it occurs freely), the variables perform the function of relative pronouns.

Although variables have been used in Indian algebra for a long time, they were not used in Nyāya. In algebra

before the introduction of variables, the pronouns *yāvat* and *tāvat* were used. In Nyāya, there is a very popular method similar to this practice which uses the relative pronouns *yat* and *tat* ('that' and 'which') and *sva* ('its', or 'one's own'). Consider the following definition: 'Pervasion is the co-presence of that with that which is not limited by the limiter of the counterpositiveness to the constant absence that has a common locus with it and has no common locus with its counterpositive.' In this definition the first 'that' stands for the probans, the second 'that' for the probandum, and the 'its' for the constant absence. (The 'its' occurs only in the translation; in Sanskrit it is eliminated by a compound.)

4 First type of definition

Two different types of definition are admitted in Navya-Nyāya, corresponding to two different purposes for which defining marks of objects are determined. The first purpose for finding a defining mark of objects collected under a mode is to find out a mark by which all the objects can be distinguished from everything else. Thus the defining mark in this case becomes the probans (corresponding to the middle term of a syllogism) for inferring that every one of the objects to be defined is different from everything else. This inference has to be for the sake of others; for according to Navya-Nyāya, the defining mark is used to prove to others that it excludes the objects to be defined, *P*s, from every non-*P*. This proof, which takes the form of an inference for the sake of others, has to be put in the negative form (see Inference, Indian theories of §5).

This point may be explained with an example. The defining mark of earth is smell. By smell all earthen things are differentiated from non-earth. The inference is of the form: 'Earth is different from non-earth, the reason being smell.' This can be put in the form of a syllogism thus: 'Whatever is not different from non-earth has no smell. Earth has smell; therefore earth is different from non-earth.' Here earth is *P* (the minor term), difference from non-earth is the probandum (the major term) and smell is the probans (the middle term).

This example shows a fundamental difference between Western theories and Indian theories in general, and Navya-Nyāya in particular. In Western philosophy, 'earth is different from non-earth' ('earth is not non-earth') is regarded as an analytical sentence. In traditional Western logic, 'earth is not non-earth' is the obverse of 'earth is earth', which is an identity sentence. But in Navya-Nyāya, no analytic sentence is significant. Although one can know (always truly) that earth is earth, there is no point in saying it, for a sentence expressing it will not communicate any information. So, according to Navya-Nyāya, there is analytical judgment, but there is no analytical sentence. But the sentence 'earth is different from non-earth' ('earth is not non-earth') is not an analytical sentence; it can be used as the conclusion of an inference. This is not true a priori; it needs to be proved. Every definition in this sense is the probans of a conclusion of the form: *P* is different from non-*P*.

5 Second type of definition

The second type of definition is used to explain why a word applies to whatever it applies to. According to Nyāya, a word becomes applicable to its referents if and only if there is a sufficient reason for its application to them. This reason must be a property of the referents, and this property is the defining property of the referents being the referents of that word. The defining mark is the nature of the referents of the word, and is denoted by the abstract noun formed from the word. For example, jarness is the nature of jars and is denoted by the abstract noun 'jarness' formed from the word 'jar' by the abstraction suffix '-ness'.

There may be different properties which belong to all and only those objects which are denoted by a word, and the problem is to decide which of them is to be regarded as the defining mark of the objects considered as the referents of the word. Not all coextensive properties are necessarily identical, even though two coextensive universals are. For example, all jars and only jars have the two properties of (1) having a neck like a conch shell and (2) jarness. Now these two properties, although coextensive, are still different, for (1) is an analysable property while (2) is not. It is to be noted that jarness cannot be used as a probans to infer that jars are different from non-jars, for here the limiting property of being objects to be defined, jarness, becomes the same as the defining mark. Thus jarness cannot be regarded as the defining mark of jars, in the first sense of the term. Jarness can, however, be the defining mark of jars in the sense of being the sufficient reason for the application of the word 'jar' to jars. In this case, the limiting property of being objects to be defined does not become identical with the defining mark, jarness, for the limiting property is not, in this case, jarness, but the property 'being the referent of the word "jar"'. In this type of definition we are considering jars only as referents of the word 'jar', and are trying to discover the sufficient

reason for its application to them.

6 Relation between the two types

There are two different motives for finding defining marks. First, when one hears the word ‘earth’, one may want to know the distinguishing mark of earth. Here the limiter of being objects to be defined is a property of the objects denoted by the word. Second, one may want to know why the word ‘earth’ is applicable to whatever it is applicable. Here the limiter of being objects to be defined is being a referent of the word ‘earth’.

There are three different theories of the relation between the two kinds of defining marks. First, the most commonly accepted theory is that these are of two different kinds. The second theory is that a defining mark in the proper sense is only a distinguishing mark; the so-called usage-explaining marks, too, can be used as probantia for inferring difference from all others by only reinterpreting the limiter of being objects to be defined as the property of being referents of the words. If this property is regarded as the limiter, then all usage-explaining marks can be used as distinguishing marks. The third theory is that a distinguishing mark can also be used as a usage-explaining mark by conceiving a usage-explaining mark as a mark whose cognition enables one to infer the correct applicability of the word. Thus there are only distinguishing defining marks, and no special type of usage-explaining defining marks.

Deism

In the popular sense, a deist is someone who believes that God created the world but thereafter has exercised no providential control over what goes on in it. In the proper sense, a deist is someone who affirms a divine creator but denies any divine revelation, holding that human reason alone can give us everything we need to know to live a correct moral and religious life. In this sense of 'deism' some deists held that God exercises providential control over the world and provides for a future state of rewards and punishments, while other deists denied this. However, they all agreed that human reason alone was the basis on which religious questions had to be settled, rejecting the orthodox claim to a special divine revelation of truths that go beyond human reason. Deism flourished in the seventeenth and eighteenth centuries, principally in England, France and America.

1 The meaning of 'deism'

Deism in the popular sense asserts that a supreme being created the world but then, like an absentee landlord, left it to run on its own. Deism in the proper sense affirms a divine creator of the world but denies any divine revelation, holding that human reason alone is sufficient to provide us with whatever knowledge is necessary for a correct moral and religious life. (The *Oxford English Dictionary* defines 'deist' as 'one who acknowledges the existence of a God upon the testimony of reason, but rejects revealed religion'.) What is the connection between the popular and proper senses of deism? Someone who believed that God created the world but left it and its inhabitants to shift for themselves would surely deny that God acted in the world to provide us with a special revelation. So a deist in the popular sense will be a deist in the proper sense. But one may be a deist in the proper sense without being a deist in the popular sense. A person who believes in God but denies divine revelation may hold, nevertheless, that human reason is sufficient to establish that God exercises providential control over his creation. Indeed, a deist in the proper sense may even insist that reason shows us that the supreme being who created the world not only exercises providential control over his creation but is also perfectly good and just and has provided for rewards and punishments for human beings in a life to come. Thus, the basic, common point that separates deists from traditional theists is the issue of divine revelation. The deist denies that God reveals to us truths that are important for us to believe but which human reason cannot discover on its own. (Some deists were prepared to allow the existence of a revelation provided that its contents were not utterly mysterious to reason, claiming that God would have no interest in revealing things to us that we could not comprehend.) This is basic deism. On top of this one may add additional items that distinguish more radical deists from the traditional theist who believes that God has provided by special revelation truths that are important for us to believe but which our reason is insufficient to comprehend or establish on its own. The deist who sees God as creator of the world but uninterested in its future and the welfare of its human inhabitants is a basic deist who has added denials of other important ideas in traditional theism.

2 Four kinds of deist

In the second series of his Boyle Lectures, delivered in 1705, the philosopher and theologian Samuel Clarke (§§1-2) distinguished four kinds of deist. The most important kind of deist, according to Clarke, believes in the existence of God in the sense of a supreme being who is infinitely powerful, all-knowing, perfectly good and the creator of the world. Furthermore, this deist believes that God exercises providential control over the world, has created human beings who have moral and religious duties, and has provided them with a future life in which the good will be rewarded and the wicked punished. But this deist rejects the idea of divine revelation, accepting only what is discoverable by natural reason. The next kind of deist holds the same view of God's attributes and providential control over the world, but in addition to denying divine revelation also denies human immortality and any future state of rewards and punishments. A further kind of deist believes that the supreme author of the world exercises control over the natural operations of the world but, lacking the moral attributes of goodness and justice, is indifferent to human welfare. It is understood that this deist also rejects divine revelation and a future state of rewards and punishments. The most radical kind of deist not only denies the moral attributes of the supreme being and any providential concern for human welfare, but also denies that the supreme being exercises control over the natural operations of the world. According to this deist, the supreme being, although infinitely powerful and intelligent, just created matter in motion without causing any particular natural happenings in the world or even establishing the natural laws according to which these happenings take place.

It is apparent from Clarke's discussion that the denial of divine revelation is common to all four kinds of deist. In his view, the most plausible kind of deism affirms that God is morally perfect and has provided for a future state of rewards and punishments. Against this kind of deist Clarke argues that it is eminently reasonable to believe that God would provide a revelation detailing our duties towards him and towards one another, particularly our need to repent of sin and establish a right relationship with him. Clarke also contends that fulfilled prophesies and the evidence for miracles rationally justify us in taking the Bible to contain this divine revelation. The next kind of deist also ascribes moral perfection to God but is encumbered with the difficulty of explaining why such a being would not provide for a future state of rewards and punishments. The last two kinds of deist deny that the creator has any moral attributes. Against both kinds Clarke argues that there are objective moral truths independent of any divine will and that, consequently, an infinitely intelligent, all-powerful being could not fail to have the moral attributes of goodness, justice and truth. For, he argues, knowing what is best to be done is itself a motive for doing it. And since God knows perfectly the principles of duty and has no needs that might conflict with his acting in accordance with duty, he always does what is best and, therefore, is perfectly good.

3 Deism's period of influence

Deism could emerge as an important movement only in a period when belief in a divine creator is not only virtually unquestioned but taken to be provable by human reason. Deism also requires a climate of enormous confidence in the power of human reason to disclose the basic truths about God, the world, morality and human destiny. And finally, deism can flourish best, if at all, only when there is general agreement that the traditions and authority of the established religion should be subject to the test of reason, and when there is some degree of toleration for different views on religious questions. In the latter half of the seventeenth century these conditions came to prevail in England, with the result that deism took root there, spreading then to Europe and America. But by the late eighteenth century its influence in England and elsewhere had declined.

The father of deism in England, Lord Herbert of Cherbury (§§3-4) (1583-1648), argued that from the very beginning of the human race God implanted in our minds a disposition to believe in the existence of a supreme being, in the obligation to worship this being by pursuing a life of piety and virtue, and in the existence of a future life in which the good will be rewarded and the wicked punished. These basic ideas he held to be at the heart of all religious traditions, constituting a universal, natural religion apprehended solely by human reason. Later deistic writers followed Herbert's lead in taking human reason as the sole source of a basic religion of nature, viewing with scepticism, if not disbelief, appeals to the authority of the Bible, the authority of the Church and its traditions, and the testimony of the inner light. Among these deistic writers in England were John Toland (1670-1722), Anthony Collins (1676-1729), Thomas Woolston (1660-1724) and Matthew Tindal (1657-1730). Toland, an Irishman, published *Christianity not Mysterious* (1696), in which he argued that nothing in Christianity that is true is either contrary to reason or above reason, attributing the mysteries in Christianity to paganism and the interests of priests. He also expressed doubts about the authenticity of parts of the Bible. His book raised such a storm that it was condemned by the Irish parliament, and he fled to England to avoid imprisonment. He professed to be a disciple of Locke, and it is instructive to compare their views. In his opposition to enthusiasm, Locke had advocated the use of reason in religion and was prepared to reject anything in Scripture that was contrary to reason. But he allowed for divine revelation of truths that were beyond reason as well as truths that were supported by reason. Thus he accepted the mysteries of the virgin birth, the resurrection and the divinity of Christ. Toland, and deists generally, departed from Locke in rejecting anything in Scripture that was mysterious or above reason (see Locke, J. §7).

The case for Christianity rested in large part on two claims: that the Old Testament prophecies regarding the messiah were fulfilled in Christ and that the miracles reported in the New Testament, particularly the resurrection of Christ, are well confirmed. If neither claim could be sustained in the court of reason, deism would appear to be intellectually superior to traditional Christianity. At least this is how the deists saw it. Consequently, they directed their attacks at the Old Testament prophecies and the New Testament miracles. In *A Discourse of the Grounds and Reason of the Christian Religion* (1724), which received thirty-five critical replies, Collins argued in some detail that on any literal interpretation of the prophecies it is simply unreasonable to see their fulfilment in the New Testament. In *Discourses on the Miracles of Our Saviour* (1727-29), Woolston attacked the argument based on the New Testament miracles. Arguing that taken literally the miracle stories were full of absurdities, Woolston claimed that even the Church Fathers recognized that they could only be taken figuratively. His work sold widely,

receiving numerous critical replies. He was fined and imprisoned for his efforts.

Tindal's influential work *Christianity as Old as the Creation* (1730) reaffirmed and developed the deists' favourite claim that God had instilled in all human beings sufficient reason to discover the simple truths expressing our duties both towards himself and our fellow human beings. Tindal argued that the fundamental teachings of Christianity express these duties and, by doing so, make Christianity as old as the creation. He proceeded to argue that this religion of nature which God wrote in our hearts from the dawn of creation is the criterion against which the teachings of all religions must be measured. Any purported new revelation must be judged by reason in light of the original religion of nature.

Voltaire, the most prominent of the French deists, came into contact with English deism during his extended stay in London (1726-9). Returning to France, he attacked both the superstition and deceit he felt to be rampant in the Catholic Church and the materialism and atheism of younger philosophers. His own deism involved a belief in God, in absolute moral values and in personal immortality. Rousseau moved from Calvinism to Catholicism and finally to deism. His deism was similar to Voltaire's in stressing belief in God and a future life, but he particularly emphasized the role of conscience in establishing a personal relationship with God.

In eighteenth-century America, the works of English religious thinkers, including deists, were well known. In the latter half of the century Voltaire and Rousseau were read. Franklin, Jefferson, Washington and Thomas Paine were deists, although Paine was far and away the most outspoken. Paine believed deeply in the existence of God and the practice of virtue. Although less concerned with human immortality, he accepted the idea of a future life. He regarded deism as the rational replacement for revealed religion and viewed the rise of atheism as a reaction to the irrationality, fanaticism and political conservatism of revealed religion. To promote deism he undertook to destroy the authority of traditional Christianity by attacking its foundation in the Bible as the revealed word of God. In *The Age of Reason* (1794) he mounted the traditional arguments against the general idea of a supernatural revelation and then focused on the claims for the Bible, arguing that Moses was not the author of the first five books of the Old Testament and that the Gospels were not written by the apostles. He denied that Jesus was divine, claiming that the life of Christ depicted in the Gospels is a fable. The great importance of Paine's book is that it brought the ideas of deism to the general public.

4 The significance of deism

In an age of reason, deism had some advantages over orthodoxy. That there is a God, that we have duties to him and our fellow humans, and that there is a future state of rewards and punishments appeared to many to be truths firmly supported by reason. Indeed, many followers of orthodoxy also held that these three points are well supported by reason. But in the fight over the need for and the existence of special revelation, orthodoxy was put on the defensive. For it was not overly difficult for the deists to point out serious weaknesses in the case for special revelation built on Old Testament prophecies and New Testament miracles. Thus, so long as reason was the only testing ground, deism appeared to have the advantage. But deism was not without problems and excesses of its own. First, deists never could agree on which beliefs were essential. Some rejected immortality, whereas others took it to be central to the religion of nature. Second, the idea that there is a fundamental, universal religion of nature common to all human beings from the dawn of creation turned out to be a myth, wholly unsupported by historical studies. And, finally, as reason's ability to settle such ultimate questions came under serious attack, deism itself was called into question. For, unlike orthodoxy, deism rejected any religious claim that could not be established by reason. Thus, although deistic beliefs (such as belief in a divine reality, belief in moral duties towards others, and so on) survive, deism's belief in the power of reason to disclose to us a universal religion of nature is largely a thing of the past.

Deleuze, Gilles (1925-95)

Although grounded in the history of philosophy, Gilles Deleuze's work does not begin with first principles but grasps the philosophical terrain 'in the middle'. This method overthrows subject-object relations in order to initiate a philosophy of difference and chance that is not derived from static being; a philosophy of the event, not of the signifier-signified; a form of content that consists of a complex of forces that are not separable from their form of expression; the assemblage or body without organs, not the organized ego; time, intensity and duration instead of space; in short, a world in constant motion consisting of becomings and encounters with the 'outside' that such concepts do not grasp.

This radical philosophical project is rendered most clearly in Deleuze (and his collaborator Guattari's concept of the 'rhizome'). The rhizome is a multiplicity without any unity that could fix a subject or object. Any point of the rhizome can and must be connected to any other, though in no fixed order and with no homogeneity. It can break or rupture at any point, yet old connections will start up again or new connections will be made; the rhizome's connections thus have the character of a map, not a structural or generative formation. The rhizome, then, is no model, but a 'line of flight' that opens up the route for encounters and makes philosophy into cartography.

1 Histories of philosophy and philosophical works

Born in Paris, Gilles Deleuze spent the period of the Second World War studying philosophy at the Sorbonne. His teachers included Ferdinand Alquié, Georges Canguilhem, Maurice de Gandillac and Jean Hyppolite. Deleuze particularly admired Alquié and Hyppolite, but found them both to be stuck in the history of philosophy. For him, only Sartre escaped that history, and introduced a breath of fresh air into the post-Liberation situation of the intellectual in France. Deleuze's academic career proceeded in the usual manner: Professeur de Lycée, Professeur de l'Université de Provence, researcher at the Centre National des Recherches Scientifiques, Professeur de l'Université de Paris VIII. His public life is perhaps defined more by what did not happen than what did. He seldom travelled outside France, never joined the Communist Party, never embraced existentialism, phenomenology, or Heidegger; but he never renounced Marx, nor was Deleuze himself denounced during the upheavals of May 1968 in France. He died in 1995, by suicide, under conditions of deteriorating health.

By his own account, all the authors in the history of philosophy who interested Deleuze had something in common: they all escaped from the history of philosophy in some respect. Beyond this they had few relationships with one another: the Stoics, Hume, Bergson, Nietzsche, Leibniz, and especially Spinoza. Their likeness had to be produced by a technique that explored what happens between them, in an encounter for which no single philosopher served as a model. In Deleuze's rewritings of the history of philosophy, as well as in his two early philosophical works, *Différence et répétition (Difference and Repetition)* and *Logique du sens (The Logic of Sense)*, what results is the production, not of history at all, but of 'philosophical geography', the line between two ideas forming an ideal space that is neither the one nor the other, but is in flux. Deleuze carries this out by grasping each philosophy 'in the middle' rather than by seeking its first principle.

An example of Deleuze's monstrous production can be found in his engagement with Kant in *La Philosophie critique de Kant (Kant's Critical Philosophy)* which he called 'a book on the enemy'. If Kant harmonizes the faculties in order to ground the architectonic of rationality, Deleuze focuses on how Kant makes possible the *disjunction* of the faculties. This incites the terrible struggle between imagination and reason and understanding and inner sense, a struggle whose importance lies in the notion that this discord produces an accord, even though the faculties are no longer determined by their succession in time or their contiguity in space, and are unregulated, as well, by any law.

Such a reading is no doubt indebted to Deleuze's admiration for Hume: not the Hume whose empiricism is claimed by the binary first principle: sensible ideas-intelligible ideas, but the Hume who substitutes the external and changing relation A *and* B, for the internal and essential relation A *is* B. Such a move realizes philosophical geography by undermining the verb 'to be' and establishing the moving series:*and, and, and*. Of equal importance, the substitution of 'and' for 'is' makes way for the concept of systems, unities or wholes that are open, as opposed to unities that transcend their parts. Finally, since philosophers have by and large begun with the concept of unity and then derived multiplicity from it as its contrary, to think multiplicity as what is, without a closed unity,

Deleuze insists that we have to learn to think in terms of time instead of space. This is Deleuze's view of Bergson's contribution to philosophy, that in the world (and equally in cinema) matter, the movement-image, is produced by the expansion or relaxation of memory-duration, the time-image. Bergson - upon whom, Deleuze remarks, so much hatred was focused within the French university - argued, against Riemann and Einstein, that duration is what differs with itself originally. It is internal difference, a world of intensive magnitudes preserved, virtually coexistent in memory as the repetition of multiple planes, and so not as a numerically multiple exteriority.

Even before Bergson, Deleuze found in Nietzsche the guarantee that memory is the return, not of 'to be', of what is the same, but of becoming and difference. Following Hume, Deleuze argues that, for Nietzsche, all bodies consist of multiple relations between forces; will to power wills becoming and difference when it experiments with forces. When a force extends its power as far as it is able, its will is the expression of the power that it is and, in willing, it affirms difference and chance.

Connecting Hume, Nietzsche, the Stoics, and especially, Spinoza, Deleuze discovered what he called 'a secret link which resides in the critique of negation, the cultivation of joy, the hatred of interiority, the exteriority of forces and relations, the denunciation of power'. What guides this is, in part, a profound and consistent anti-Hegelianism. In *Le Bergsonisme (Bergsonism)* this anti-Hegelianism is oriented by Bergson's objection to the imprecision and generality of Hegel's notions of unity and multiplicity. In *Nietzsche et la philosophie (Nietzsche and Philosophy)* it is guided by Nietzsche's critique of negative slave morality, values based upon a logic that states, 'You are evil; therefore, I am good', and upon the false conception of action as external rather than internal to power. This critique is clarified in Deleuze's work on the Stoics and Spinoza, where it is played out in terms of a conception of the body as multiple and active.

For the Stoics, there are two planes of being: bodies and events. Bodies are beings in depth; they are real, existing in space and temporally, in the present. On the other plane, we find 'incorporeal acts' - sense, the formalization of expression, ideational events at the surface of bodies. Mixtures deep inside bodies are the *causes* of incorporeal events, that is, of sense: becoming green, becoming poisoned. These becomings are the effects of bodily mixtures and are not reducible to bodies. Deleuze's logic of becoming undermines propositional logic, for the attribute is not a quality related to a subject by the indicative 'is'; any verb in the infinitive operates as limitless becoming. This has the additional effect of referring to no subject, no I claims the event which is always referred to simply as 'it'.

Deleuze wrote two books on Spinoza: *Spinoza et le problème de l'expression (Expressionism in Philosophy: Spinoza)* which served as part of his doctoral thesis, and *Spinoza: philosophie pratique (Spinoza: Practical Philosophy)*. For Deleuze's project of geographical philosophy, Spinoza's importance lies in the fact that, practically alone among philosophers, Spinoza asks what a body, understood as an assemblage of affects or becomings, can do, and how this leads to the practical or ethical question of how to increase our power to think, exist and act. The answer is, on Deleuze's account, a matter of a body's capacity to be affected in encounters among bodies, each of which is a dynamic and open multiplicity, an assemblage. Bodies that are compatible increase one another's power to act; incompatible bodies decrease power for one or both of them. As a decrease in power is the normal situation for human beings, so the 'sadness' that characterizes the human condition is the first point of attack. On the practical or ethical level, Deleuze-Spinoza recommends a two-pronged approach: first, devalue sad passions; second, carry out an analysis of the systems of relations of the parts of bodies to determine which relations are compatible. This sparks the production of a geography that moves from merely joyful passive affections, to compatible relations as the cause of joy and finally, to the Spinozan ethical imperative: become active!

2 Collaborations with Félix Guattari

In 1969, Deleuze met Félix Guattari, a practising psychoanalyst and political activist. They collaborated on explosive and radical books of philosophy: *Capitalisme et schizophrénie (Capitalism and Schizophrenia)*, *L'Anti-Oedipe (Anti-Oedipus)*, *Mille Plateaux (A Thousand Plateaus)* and *Qu'est ce que la philosophie? (What is Philosophy?)*. In this collaboration, an assemblage was constructed: 'Since each of us was several, there was already quite a crowd', and the geography of the encounter was practised: 'We are no longer ourselves', 'We have been aided, inspired, multiplied.' *Anti-Oedipus* is less an argument against the idol of psychoanalysis than a

demonstration of the relation between, on the one hand, the herd instinct and the desire to be led that motivates those who profess their faith in Oedipus or in the state; and on the other, state fascism and the fascism we all carry with us.

Deleuze and Guattari address the key question posed by Wilhelm Reich: 'How could the masses be made to desire their own repression?' They hypothesize that fascism is lying in wait wherever the judgment 'He is evil, so I am good' is made and wherever what they call *lines of escape* or deterritorialized flows of desire, have been reduced to state, family or religious hierarchies. In the first case, we recognize what Nietzsche condemned as base valuations that can end only in nihilism. In the second, we find state institutions, hierarchies committed to binary thinking and dedicated to limiting or breaking the connections that allow for the construction of the multiplicity known as the assemblage, as well as heading off encounters between assemblages.

A Thousand Plateaus operates on many planes at once. Thus it serves as an embodiment of the open whole, which Deleuze and Guattari now call the 'rhizome'. Each chapter or 'plateau' of this book can be read independently of any other, and each is accompanied by a date, though in no particular order and not always of importance in any traditional history: the date of Freud's analysis of the Wolf-man, the date the *Reichsmark* was declared to be no longer money, the date of the destruction of the Jewish Temple, the date of vampires. These dates or events take their place in various *semiotic* systems, some of which are linguistic and some not. But they never appear in the despotic linguistics of the signifier-signified relation, wherein all aspects of life are reduced to language. For, even when Saussure's linguistics released the signified (concept) from any constant relation to the word or sound image, it did so only by elevating the signifier, insofar as the relations between signifiers always determine the value (meaning) of any signified (see Saussure, F. de).

If meaning-events are the effects of bodies, then an entirely different relation between bodies and linguistic systems has to be established. If, following Nietzsche, a thing has as many meanings as there are forces capable of seizing it, and if each force consists of a complex of other forces, then in place of the old dualism of substance and form Deleuze and Guattari assert two substance/form complexes: one of content and one of expression. These two assemblages of forces cannot be separated from one another. A distinction between form of expression (an order and organization of functions) and form of content (an order and organization of qualities) can only arise for purposes of analysis: for example, in the encounter between a nomad war machine (form of expression) and itinerant metallurgy (form of content). Nor is the encounter necessarily or even primarily linguistic - linguistics is merely one of many semiotics, and not the most important.

The role of language and the task of philosophy regarding language are also crucial to *What is Philosophy?*, the end of the experiment between Deleuze and Guattari, an end sealed by Guattari's death in 1992. In this book, the Stoic treatment of bodies and events implicit throughout *A Thousand Plateaus* re-emerges forcefully, as Deleuze and Guattari argue that the task of philosophy - as opposed to science - is the creation of concepts, the extraction of events from beings and things so as to create a plane of immanence, a plane of consistency. For philosophy does not seek an external plane of reference or truth, as science does. The distinction between bodies and events is important here, for while philosophical concepts are constituted from immanent variations of consistent events, scientific functions refer to states of affairs or mixtures in bodies. Thus, while philosophical concepts are enunciated by conceptual personae (the friend, the stammerer) that are not the philosopher, but that trace out the line of becoming that is the concept, scientific functions are enunciated by the scientific observer situated within the perspective of a particular state of affairs (the relativity traveller).

3 Minor literature and nomad arts

Given Deleuze's interest in the history of philosophy and in social and political philosophy, his careful attention to literature and the arts may be unexpected. Yet, his two books on cinema, books on Sacher-Masoch and Sade, Kafka, Proust and Francis Bacon, as well as articles and constant references to a host of literary, musical, and artistic works and persons all evidence the central role of literature and the arts to philosophical geography. Thus, there is *Le Pli: Leibniz et la baroque (The Fold, Leibniz and the Baroque)* celebrating the pleat, the curve, the twisting surface of science and mathematics, but also of music, architecture, the line and the word; a sensuous view of the world that lives in the work of art. Nomad arts are blocs of sensations or a 'fold'. Each is a compound of percepts and affects wrested from the subject and its states by means of the material of each art. By means of its material, words and syntax, affective writing is the becoming-multiple that deterritorializes a major language and

produces minor writing, which is the composing and decomposing of saturated percepts, rather than a record of memories, fantasies or travels. Thus, everything that is written takes its place within the open whole which is the social world. Likewise, cinema is sensation conditioned by cinema's plastic mass of visual material that puts into operation the open whole as both incessant flux and instantaneous disjunction. In place of language, art gives us percepts, affects and blocs of sensation put into motion. This is not philosophy, yet it makes philosophy happen by giving the event a body, a life, a universe.

Delmedigo, Elijah (*c*.1460-93)

Throughout the treatises and translations commissioned by his many patrons in Italy, Elijah Delmedigo championed Aristotle and Ibn Rushd (Averroes). In Latin texts prepared for Pico della Mirandola, Delmedigo affirmed such cardinal Averroist notions as the absolute unity of all human minds and the role of God as the unmeditated principle of intelligibility in the universe. In the Hebrew Behinat ha-Dat (The Examination of Religion), Delmedigo urges the superiority of a rationalistic Judaism over other religions, especially Christianity, and over the nonphilosophic, improperly philosophic and antiphilosophic versions of Judaism. Sections of this work amount to a nuanced critique of Kabbalah. Combining ardent Averroism with qualified admiration for Maimonides, Delmedigo repeatedly argued for the compatibility of Judaism with secular philosophic speculation.

Born to a distinguished family of rabbinic scholars and intellectuals in Candia on the island of Crete, Delmedigo migrated to Italy in 1480. He spent the next ten years expounding and defending Ibn Rushd's controversial version of Aristotelian philosophy (see Ibn Rushd; Averroism, Jewish). Residing mainly in Padua, Venice, Bassano and Florence, Delmedigo was commissioned by such figures as Girolamo Donato, Domenico Grimani, Antonino Pizzamano and the Neoplatonic enthusiast of Kabbalah, Giovanni Pico della Mirandola, to translate Hebrew versions of Ibn Rushd's texts into Latin and to write systematic accounts of the latter's views. Seeking a wider audience, Delmedigo translated at least three of his own Latin works into Hebrew: two treatises dealing with the unicity of the hylic intellect and conjunction with the 'active intellect' - *Shete she'eloth 'al ha-Nefesh* or *Shene derushim 'al Hanefesh (Two Questions on the Soul)* - and *Ma'amar 'al 'etzem ha-Galgal*, his exposition of Ibn Rushd's *De Substantia Orbis (On the Substance of the Celestial Sphere)*. Slavishly literal, these Hebrew translations differ from Delmedigo's Latin originals only by the interpolation of autobiographical data and discussions of religious topics that Delmedigo considered relevant to the Jewish community.

In the late 1490s, Delmedigo returned to Crete and began writing *Behinat ha-Dat*. He faulted Christianity for its irrational dogmas and excoriated Jewish mystics for their excessively Neoplatonic metaphysics and 'idolatrous' interpretations of Jewish ritual observance. He also chided Maimonides and other unspecified rationalist theologians for confounding religious faith with philosophic speculation. Framing his criticism of the revered Maimonides diplomatically, he blamed him and the others for undermining social unity with their rationalist interpretations of religion. To avoid sectarian strife, Delmedigo counselled against publication of written doctrinal interpretations of Scripture and the law. He also argued that it was imprudent to convey the mistaken impression that religious belief and practice are rationally grounded rather than prophetically instituted.

Delmedigo was nevertheless eager to establish the compatibility of Judaism and philosophy. He emphasized the congenial parallel between Talmudic logic and philosophic argumentation, explaining that just as the rabbis use a set of well-defined principles for drawing inferences from Scripture, so the philosophers use syllogisms for reaching demonstrative truths. Delmedigo was intent on mitigating conflicts within the Jewish community. He balanced his trenchant criticisms of the Kabbalah by lacing *Behinat ha-Dat* with conciliatory remarks addressed to the Jewish mystics, highlighting the accords of Kabbalah, rational belief and popular religion.

Averroists are notoriously difficult to pin down; their utterances often seem inconsistent or contradictory. Their explications of Aristotle can be read as detached scholarship or partisan advocacy. They are known for tolerating what they deem to be mistaken popular beliefs that preserve the social order. Their overriding concern sometimes seems to be to make society safe for philosophy. The elusive Delmedigo was no exception. Most of his writings are not systematic statements of his own philosophy. Rather, they are secular commentaries and polemical treatises expounding Aristotle as interpreted by Ibn Rushd, who was, in turn, often misunderstood by the likes of John of Jandun, a Latin Averroist whose many mistakes in interpretation Delmedigo seldom failed to mention and correct. Extracting Delmedigo's own convictions regarding physics, metaphysics and political philosophy from exegetical sources of this kind is difficult. *Behinat ha-Dat* is not as direct a help as we might wish. It was motivated as much by a diplomat's eirenic 'love for the words of our Torah, for our sages, and for the people of our nation' as it was by a medieval philosopher's austere devotion to logic, reason and truth. Knowing how anxious Delmedigo was to keep the peace makes it hard to determine where his devotion to Aristotelian philosophy ends and his love for Judaism begins.

Regardless of motive, Delmedigo unequivocally declared Aristotle the supreme philosopher and Ibn Rushd his only trustworthy commentator. With equal tenacity he affirmed philosophy and Judaism to be compatible, but only ‘when they are properly understood’. These philosophical commitments put him at loggerheads with most of his contemporaries. Expounding Ibn Rushd’s controversial monopsychism and its corollary, impersonal and unindividuated immortality, Delmedigo affirmed two of the most notorious doctrines against which Thomas Aquinas and other theologians had argued vehemently. Defending Ibn Rushd’s understanding of God as a self-sufficient mind whose rationality constitutes the unmediated principle of intelligibility and regularity in the universe, Delmedigo staked out his position among a heroic minority. Arrayed against him were Italian Neoplatonists and Kabbalists who embraced the metaphysics of emanation. Opposed to him also were obscurantists, who ridiculed philosophy, and scholastic theologians of all creeds, who defended radically voluntaristic doctrines of God’s utter transcendence, unfettered will and direct awareness of particulars.

Delmedigo’s enduring contributions to philosophy are twofold: he defended the secular autonomy of philosophy, its right to follow its own course, free of theological preconditions; and, if we take him at his word, he legitimized philosophy by stressing its power to establish and maintain civil order - without which philosophy itself would be unattainable.

Demarcation problem

The problem of demarcation is to distinguish science from nonscientific disciplines that also purport to make true claims about the world. Various criteria have been proposed by philosophers of science, including that science, unlike 'non-science', (1) is empirical, (2) seeks certainty, (3) proceeds by the use of a scientific method, (4) describes the observable world, not an unobservable one, and (5) is cumulative and progressive.

Philosophers of science offer conflicting viewpoints concerning these criteria. Some reject one or more completely. For example, while many accept the idea that science is empirical, rationalists reject it, at least for fundamental principles regarding space, matter and motion. Even among empiricists differences emerge, for example between those who advocate that scientific principles must be verifiable and those who deny that this is possible, claiming that falsifiability is all that is required.

Some version of each of these five criteria - considered as goals to be achieved - may be defensible.

1 What is the problem and why is it raised?

'The problem of demarcation' is an expression introduced by Popper to refer to ' the problem of finding a criterion which would enable us to distinguish between the empirical sciences on the one hand, and mathematics and logic as well as "metaphysical" systems on the other' ([1934] 1959: 34). Although Popper mentions mathematics and logic, other writers focus on distinguishing science from metaphysics and pseudoscience.

Some, including Popper, raise the problem because of an intellectual desire to clarify this distinction. Logical positivists had in addition the aim of overthrowing non-scientific disciplines such as metaphysics and theology that purport to describe the physical world but, being unverifiable, are (they claimed) lacking in meaning. Others have more practical aims. In a country such as the USA, which officially attempts to separate church and state, religion is not to be taught in the public schools, but science is. So the practical question becomes what to count as science (for example, is 'creation science' appropriately named?).

2 'Science is empirical'

Metaphysics, philosophy and theology are not. What this means, however, can vary from one view to another. On one typical account, science consists of propositions (such as the law of conservation of energy) that are either directly verifiable by sensory observation, or can be inferred from such observations by the use of inductive reasoning from observed members of a class to all members, or are derivable from either of these using deduction. By contrast, the propositions of metaphysics (for example, 'Platonic universals exist') fail to satisfy these criteria. Newton, who held such an empiricist view, claimed to derive his three laws of motion and law of gravity from observed phenomena using induction and deduction (see Newton, I. §4). Similar views have been held by many empiricists, including J.S. Mill and the logical positivists. A significantly different empiricist view is espoused by Popper, who, following Hume, regards inductive reasoning as lacking in logical justification. For Popper, although scientific laws cannot be verified inductively, they can be falsified by observing a single negative instance; accordingly, falsifiability by observation, rather than verifiability, is what makes science empirical (see Popper K.R. §2).

Although the vast majority of influential writers on science have held that scientific propositions are empirical, there are significant exceptions, especially as regards fundamental principles involving space, matter, and motion. Descartes believed that the most basic principles of physics (no less than those of metaphysics) are knowable a priori by the use of rational intuitions and deductions from them (see Descartes, R. §7). Other a priorists include Kant, who asserted that these principles are synthetic a priori (see Kant, I. §7), and Poincaré, who defended them as conventions of language (see Poincaré, H. §§3-4). Whewell suggested a mixed view according to which, although scientists must first arrive at propositions empirically, as their scientific ideas become clarified they realize that these propositions are necessary and knowable a priori (see Whewell, W.).

3 'Science seeks certainty'

In this respect it is like mathematics and unlike metaphysics, theology and astrology, which, it is alleged, can never

be more than speculative. In his *Regulae ad directionem ingenii (Rules for the Direction of the Mind)* (1620-*c*.9) Descartes' second rule is that 'we must occupy ourselves only with those objects that our intellectual powers appear competent to know certainly and indubitably'. Empiricists are more divided. Newton, who rejected Descartes' idea that science should aim at indubitable propositions, recognizes in his fourth rule of scientific method that any proposition, no matter how strongly supported, is liable to exception as further phenomena become observed. Nevertheless, scientists should always aim at the highest certainty possible in an empirical endeavour, which is obtainable by 'deducing propositions from phenomena and rendering them general by induction'.

Among empiricists at the other extreme from Newton are Popper and Laudan. For Popper a high degree of certainty is not possible in science since the use of any inductive generalizations that might generate such certainty is unjustified. Nor is it desirable, since scientists should make the strongest possible and hence the least likely generalizations. For Laudan (1977) science aims at providing 'adequate' solutions to 'interesting' problems, for which questions of truth, certainty and even probability are irrelevant.

An empiricist view that lies between these extremes is taken by Carnap and other probabilists. Scientists should aim at providing empirical evidence for a theory that increases its probability without necessarily rendering it high (see Achinstein 1983 for a critique).

4 'Scientists follow a scientific method'

Practitioners of non-sciences do not. A scientific method is a set of rules scientists should follow in discovering and testing laws and theories. Whether there are such rules and if so, what forms they take, whether they are universal for all sciences or even within a science, whether they change from one period to another, are all hotly disputed questions (see Scientific method).

On one view, there are rules for testing scientific theories that hold for all science during all periods. This view was espoused by Descartes, who proposed twenty-one such rules; it was also championed by the empiricist Newton (1687), who proposed four 'Rules of Reasoning in [natural] philosophy', comprising two for inferring causes of things, and two for making inductive generalizations from observed phenomena.

The two most prominent empiricist positions committed to a universal scientific method are hypothetico-deductivism and inductivism. According to the former, the scientist confronted with data and a problem begins by proposing an hypothesis, which is not inferred deductively or inductively from the data or anything else, but is simply offered as a conjecture. From it, and possibly other assumptions, observational conclusions are generated deductively, using logic and frequently mathematics. If the conclusions are established by observation the hypothesis is tentatively accepted. If they are found to be false, the hypothesis is rejected and a new one proposed. This is Popper's view.

By contrast, inductivists require one further step, an inductive argument giving independent support to the hypothesis or theory. This involves arguing from observed instances of a law to all cases or from similar effects to similar causes. Inductivists such as Newton and Mill reject the hypothetico-deductive method on the grounds that numerous conflicting hypotheses can entail the same data; what is required is independent inductive support for one of these.

The existence of a universal scientific method has been challenged by several twentieth-century writers, particularly since the 1960s. Thomas Kuhn (1962), arguing for a historical, relativistic approach, asserts that scientists at a given time work within a 'paradigm' which consists of a set of concepts, practices, standards of evaluation, rules of reasoning and methods of observation that vary considerably from one science and period to another. The paradigm sets the problems to be solved and the methods for doing so. There is no scientific method common to all paradigms.

Finally, a sociological approach to science has been advocated (see, for example, Pinch 1986), a strong version of which rejects appeal to methodological rules in explaining how scientists proceed. Theories, being underdetermined by the data (see Underdetermination), are not inferred from those data by using rules. One must look instead at social factors within the scientific community that explain how a scientific theory is developed and how the group 'negotiated' to accept it (see Constructivism).

5 ‘Science describes only the observable world’

Metaphysics, theology and even mathematics describe worlds underlying, or beyond, or independent of, what can be observed. This is a view upheld by instrumentalists and other ’antirealists’ and rejected by realists. Antirealists claim that the aim of science is to ’save the phenomena’ by formulating theories that will correctly predict what is observable. Some antirealists, for example, Duhem and van Fraassen, believe that an unobservable world exists, but deny that the aim of science is to describe it. For Duhem that is the aim of metaphysics and theology (see Duhem, P.M.M. §4). Other antirealists, for example, logical positivists of the 1950s and 1960s, held a strong form of instrumentalism, according to which claims about unobservables in science are to be construed, not as speaking of real entities, but as linguistic devices in a theory for generating claims about what can be observed. For these writers both science and metaphysics introduce terms for unobservables that do not denote objects in the world. The difference between the two disciplines is that scientists but not metaphysicians tie these terms to observables in such a way as to allow observational predictions.

Realists, by contrast, claim that there is a physical world that exists independently of our minds, our observations and our theories. This world contains not only things and events scientists can observe (for example, the planets), but ones they cannot (for example, quarks). The job of the scientist is to describe both the observable and the unobservable worlds. To accept a theory involves a commitment that what it says about both is true. For the realist the distinction between science and metaphysics is not to be drawn by saying that science, but not metaphysics, describes the observable (see Scientific realism and antirealism).

6 ‘Science is cumulative and progressive’

Metaphysics, theology and philosophy are not. The history of philosophy, for example, is just the history of one theory after another; the more different the new theory from the old, the more it conflicts with it, the better its chance of being taking seriously. Science, by contrast, develops in an incremental, progressive way, so as to retain and build upon much of what has come before. In addition, as science advances it yields more and more truths about the world (or saves more and more phenomena); philosophy does not.

This idea, forcefully defended by logical positivists, came under strong challenge in the 1960s particularly from Feyerabend and Kuhn. Both argued that a predecessor theory is usually not derivable from a successor. Sometimes, as Feyerabend (1993) noted, the two are not even logically compatible. Sometimes the two are ‘incommensurable’: they use concepts that completely depend for their meanings on different theories and that cannot be translated from one theory to the other. For Kuhn this occurs when, as in Newtonian and relativistic mechanics, the theories are parts of different paradigms (see Incommensurability).

7 Is a criterion of demarcation possible?

One might suppose not, in view of such controversies over what constitutes science. Indeed, even the need for a demarcation criterion has been challenged by some philosophers, especially ones who think that philosophy itself is or ought to be construed as part of science (for example Quine 1973).

Nevertheless, we do tend to distinguish science from other disciplines. Newton’s mechanics is a scientific theory, but his theory of scientific method is not; it is a philosophical theory. One helpful step might involve taking science, or even a particular science such as physics, at a given historical time and saying something general about the goals of practitioners at the time, while recognizing that these may change and that not all scientists accept them. With this in mind, we might say that the previously quoted claims reflect scientific goals to be achieved at some point.

For example, in modern physics as well as other sciences, a goal is to present empirically testable ideas - even if at the moment (as with superstring theory) it is not known how to test the ideas empirically. For J.J. Thomson, who in 1897 claimed that cathode rays are charged particles not waves, it was not enough simply to postulate that this is so. He wanted to show how in principle this claim could be tested empirically by demonstrating that the rays can be electrically deflected, something that had not previously been accomplished. The goal of making hypotheses empirically testable is one generally shared by physicists but not by philosophers. Physicists can be just as speculative as metaphysicians, but they cannot be so for too long.

Another goal is to achieve certainty, at least as much as possible, by actually carrying out such tests. Although philosophers, theologians and mathematicians may also crave certainty, their route to it is a priori argumentation, not empirical testing. (For a contrary viewpoint regarding the status of philosophy of science, see Donovan *et al.* 1988) This is related to two further goals. Even if both physicists and metaphysicians postulate 'unobservable' entities, one of the aims of physics, but not metaphysics, is to eventually render them 'observable' - to detect and measure them. It was not sufficient for Thomson simply to postulate the existence of the particles (electrons), or even to describe an experimental procedure for electrically deflecting them and measuring their mass to charge ratio. He also attempted (successfully) to perform the experiment. Nor was this the end of the matter. Thomson sought to *argue* for his theory of charged particles from the results of his experiments. He did so, as Newton and Mill suggest, using both deduction and inductive generalization (see Achinstein 1991). Achieving as much certainty as possible through empirical testing requires the use of logical arguments in accordance with a 'scientific method'. Without such arguments mere 'negotiation' within a group is not enough.

Finally, physics today is much more cumulative and progressive than metaphysics or other fields of philosophy. A physicist may present completely new ideas, but in working out consequences it is desirable to make use of general principles, such as conservation laws, that are empirically established. Otherwise deductions to testable conclusions would be much rarer than they are. Even in contemporary philosophy, by contrast, few if any general principles are considered by most philosophers to be established.

Assuming these represent goals of many physicists (but not of philosophers or other 'non-scientists'), a job for philosophers of science is to provide a critical, systematic account of them. Philosophers of science may also try to determine the extent to which these goals, so clarified and systematized, can be attributed to scientists in other fields and at different times.

Democracy

Democracy means rule by the people, as contrasted with rule by a special person or group. It is a system of decision making in which everyone who belongs to the political organism making the decision is actually or potentially involved. They all have equal power. There have been competing conceptions about what this involves. On one conception this means that everyone should participate in making the decision themselves, which should emerge from a full discussion. On another conception, it means that everyone should be able to vote between proposals or for representatives who will be entrusted with making the decision; the proposal or representative with most votes wins.

Philosophical problems connected with democracy relate both to its nature and its value. It might seem obvious that democracy has value because it promotes liberty and equality. As compared with, for example, dictatorship, everyone has equal political power and is free from control by a special individual or group. However, at least on the voting conception of democracy, it is the majority who have the control. This means that the minority may not be thought to be treated equally; and they lack liberty in the sense that they are controlled by the majority.

Another objection to democracy is that, by counting everyone's opinions as of equal value, it considers the ignorant as being as important as the knowledgeable, and so does not result in properly informed decisions. However, voting may in certain circumstances be the right way of achieving knowledge. Pooling opinions may lead to better group judgement.

These difficulties with democracy are alleviated by the model which concentrates on mutual discussion rather than people just feeding opinions into a voting mechanism. Opinions should in such circumstances be better formed; and individuals are more obviously equally respected. However, this depends upon them starting from positions of equal power and liberty; rather than being consequences of a democratic procedure, it would seem that equality and liberty are instead prerequisites which are needed in order for it to work properly.

1 What democracy is

Democracy means rule by the people. It is a form of decision making or government whose meaning can be made more precise by contrast with rival forms, such as dictatorship, oligarchy or monarchy. In these rival forms a single person or a select group rules. With democracy this is not so. The people themselves rule and they rule themselves. The same body is both ruler and ruled.

Philosophical accounts of democracy analyse its nature and discuss its value. The two cannot be completely separated. Any account which explains the value of democracy has to provide or presuppose an account of what it is holding to be of value. Conversely, supposedly neutral analyses of the nature of democracy are influenced by values. For example, someone who thinks that democracy is a good thing is liable to analyse it in terms of other features also thought to be good.

The concept of democracy therefore may naturally be thought of as what W.B. Gallie called an essentially contested concept. Such concepts are concepts whose analysis is unresolvable because different analysts read into it their favoured values. For example, before the reunification of Germany, both East and West Germany called themselves democracies. Yet each had very different political systems, one being a Marxist single-party state, the other having economic and political competition with several parties and contested elections. A dispute about which one was really a democracy would be irresolvable.

This account and this example presuppose that democracy is desirable, so there is a competition to lay claim to the honorific title. However, for most of the time since the invention of the concept of democracy it has not been taken to be a term of honour. A kind of democracy did exist in ancient Athens. But, this was a form of government criticized by the leading Greek thinkers of the time, Plato and Aristotle. For most of the time since this early democracy ended, democracy has neither existed nor been thought to be desirable.

Much later, with the creation of the USA, we reach a system which most people today would take to be a paradigmatic example of democracy. Unsurprisingly it was defended by its founding fathers. However, what might surprise us more today is that in one of the most famous of these defences, James Madison was careful not to use

‘democracy’ as the name for the system he supported. He identifies things called democracies and does not support them; the description he uses instead for the fledgling USA is ‘republic’ (Madison, Hamilton and Jay 1787-8).

What Madison means by a republic is ‘a government in which the scheme of representation takes place’, and by a democracy ‘a society consisting of a small number of citizens, who assemble and administer the government in person’ (Madison, Hamilton and Jay [1787-8] 1987: 126). It might be thought that the central question here is one of size. Commentators writing just before Madison, such as Rousseau (§3) (1762) and Montesquieu (§3) (1748), held that democracy was only possible in small states; and Madison can be taken to be marking the transition to the modern world, with large states rather than small ones; and a corresponding move from direct democracy to representative government. What is today standardly called democracy is very different from what was standardly so called in the ancient world.

However, size is not the only important distinction here. Individuals in very large modern political units can now be so linked together by modern technology that they can relate to each other much as if they all met together. On the other hand, political decisions by and for small groups are still made in the modern world. It can still be asked of these whether they should be made democratically; and, if so, which sort of democracy is appropriate. So, whatever the size of political unit, questions can arise about the importance of participation or discussion before decisions are made. It can be asked whether democracy should be seen primarily as a mechanism in which people vote for policies or representatives without assembly, participation or discussion. At one extreme (as with Joseph Schumpeter (§3) (1943)), we could analyse democracy as a competition for votes between professional politicians. At the other extreme, we could analyse democracy as a system in which unanimous decisions are reached after a prolonged discussion which respects the equal autonomy and participation of everyone involved. The former seems more practical, but may not uphold any (other) ideals; the latter seems impressively ideal, but may be ineffective in practice.

It has just been said that voting and representation is at least practical. However, this ignores one prominent problem. This is that the collective view which results from voting may not be related in the way we would wish to the individual views expressed in the votes. In particular this applies if there are three or more options to be arranged in order of preference and there are three or more such individual orderings (see Social choice). These problems will not be discussed further here; although it should be recognized that many people (such as W.H. Riker (1982)) think that they are an insuperable objection to democratic decision making.

2 The value of democracy

Once we have an idea of democracy, the next question is why, or whether, it is of value. The Greek historians identified the original introduction of democracy with the advance of liberty and equality. Since both liberty and equality are usually thought to be of value, this would seem to be a natural answer to the question. Democracy is of value because it produces liberty and equality. With dictatorship or other forms of special leadership, a particular person or group has more power than others. By contrast, in democracy everyone is equal. Everyone has the same (political) power. So democracy is egalitarian as compared with other forms of government or decision making.

Similarly for liberty. A democracy introduced by the overthrow of a dictator increases political liberty. People have been freed from the control of the dictator. Hence democracy promotes liberty. There are several connected terms here: liberty, freedom, autonomy. However, whichever term is used, this argument seems to work. Consider autonomy. It means, literally, self-rule. Yet this is exactly what happens in democracy, as opposed to other forms of government. The people rule themselves.

However, as always, further inspection makes matters less obvious. Suppose decisions are made by majority vote and someone is in the minority. This person is outvoted and so their wants will not be put into effect. Therefore we can question whether in this (democratic) situation, this person is really autonomous. They are being made to do something which they do not want to do. Hence they are not really autonomous. Similarly for equality. Not everyone is treated equally when majority decisions are adopted, because only the views of some people (the majority) are put into effect. The minority’s views are disregarded. Hence they are not treated equally. The winner takes all, and hence winners and losers are not equally treated.

If a community is divided into two parts living in mutual antipathy, this becomes even more obvious. The majority

community could, by democratic vote, bear heavily down on the minority community, restricting or removing things it holds to be of fundamental value. In such circumstances the members of the minority community could hardly be said to be at liberty; nor could it be said that they were being equally treated. Hence the phrase, used by Tocqueville (1835) and taken over by J.S. Mill (1859), 'the tyranny of the majority'. The initial contrast between democracy and dictatorship has now been left behind. If democracy is really the dictatorship of the majority, then it is not so obvious that democracy promotes freedom and equality.

3 The paradox of democracy

If we examine democracy from the standpoint of the minority, as in the last section, this helps to focus the problem of its value. A democrat thinks that the majority view ought to be enacted. But in voting they also declare their own view about what ought to be enacted. When they are in a minority these diverge and they seem to be caught in a contradiction. There are two incompatible policies, A and not-A. Yet the minority democrat seems to think both that A ought to be enacted (because that is what the majority want) and also that not-A ought to be enacted (because that is their own view). Richard Wollheim (1962) called this the 'paradox of democracy'.

However, if democracy can be given a value, the paradox is resolvable. For what we then have is a simple (and familiar) conflict of values. The democrat's direct view of the matter indicates the value of the course of action for which they voted. But once it is defeated by the majority this rival course of action also possesses value. For it inherits the value of democracy. If, for example, democracy is taken to be an egalitarian procedure then adopting this rival course of action has egalitarian value.

An example: four of us in a car have to decide to go either to the beach or to the town. There is only one car and we can go to only one place. We agree to decide democratically, by vote. The vote is taken. I vote for the beach, and am outvoted by three to one. The beach is of value to me. This is shown by my vote. However, I am also a democrat. After the vote, the town also has value to me. With the town three people's views are respected; with the beach only one. If I hold that people are of equal value, then I have a reason for the car to go to the town.

4 Democracy and knowledge

In his *Republic* Plato says that 'it is not in the natural course of things for the pilot to beg the crew to take his orders' (*c*.380-367 bc: 489b). The implication is that if we want as a group to go to the right place, it is not sensible to assume that everyone has an equally valid opinion. Instead we should follow the lead of those who know. Hence democracy, which treats everybody's opinions equally, is inefficient as a means of determining the right thing to do (see Plato §14).

This argument makes several presuppositions and can be resisted by contesting them. Some people can only know more than others about something if there is indeed something to be known. That is, if there is a truth about the matter independent of people's opinions. But this is precisely what might be contested when the question is what the state should do. This being a matter of value, it might be held that no independent truth, and hence no knowledge, is available. More precisely, it might be thought that a line can be drawn between areas in which knowledge is available, and which, for example, might be handled by a professional, trained civil service; and areas for which no knowledge is obtainable, and which should be left to democratic, untrained, amateur decision. Benjamin Barber (1984), for example, takes the area of politics to be one of action, not truth; and for him democracy takes over in the areas where metaphysics fails, creating its own epistemology.

It should be noticed, however, that an argument for the goodness of democratic decision making cannot simply be made on the basis of a complete scepticism about values. For if no truths about values are available, then no truths about the value of democracy are available either. Hence a valid argument cannot be made from this premise to a conclusion that it is true that democracy is of value.

Conversely, even if it is allowed that there are independent truths about value, it does not directly follow that democracy is an inappropriate way of discovering these truths. For it is quite possible that the truth about what in general the state should do is the kind of truth about which people have a roughly equal capacity. Furthermore, even if people do not have equal capacity, as long as it cannot be told which ones are superior, democracy may still be the appropriate method to use. The Platonic argument assumes that there is a truth about what should happen; that this truth is better known to some people than others; and that it is possible to tell independently of

their views which these people are. All these assumptions could be resisted.

If people are of roughly equal capacity (or it cannot be told who is superior) then, as long as everyone is more likely than not to be right, voting and adopting the majority view is an efficient method to use. For the majority decision has a higher probability of being right than any individual decision, as Condorcet (§2) was the first to show. In other words, if I have to make a sequence of decisions about the truth of something and I am in a group each of whose members gets the answer right more often than not, then I do much better systematically following the majority view of the group than my own initial views.

Even if some people clearly have better informed views than others, it still does not follow that democratic decision making is inefficient. For if it is obvious who the experts are, then people with an interest in discovering what is right will generally follow their views. In other words, the same answers will be arrived at as would happen if, as in Plato, the better informed were made dictators. Democracy will not be inferior in discovering of the truth, and will have other advantages.

On the other hand, if it is not obvious who the experts are, then it is indeed the case that the majority view may not follow expert opinion. But, if some people are dictators, it may also be the case that the people who are made dictators are not the ones who are better informed. The dangers of mistake in following majority opinion are matched by the dangers of mistake in making the wrong people the dictators. The Platonic argument only works if the experts can be recignized in advance, for example (as in Plato’s *Republic*), because they are educated in a way which ensures that they will have expertise.

5 The use of democracy

Other justifications for democracy are possible. One standard device for justification, for many areas, is utilitarianism (see Utilitarianism). Something is justified if it promotes general happiness or utility. It can be asked of a form of government, just like anything else, whether it does tend to promote this. The answer, at least of the classical utilitarians such as Bentham (§6) and James Mill, is that democracy does.

This argument is expressed most simply in James Mill’s short essay, *Government* (1820). He starts with an evaluative and a factual premise. The evaluative premise is utilitarianism. Actions are right in so far as they promote the general happiness. The factual premise is universal self-interest. People seek those things which promote their own interests. The problem is to find the form of government in which both of these premises can be true together, to find the form in which people seeking their own interest will nevertheless do those things which promote the general happiness. It is not difficult to show that representative democracy is the answer. Kings will promote the interest of kings, dictators of dictators, oligarchies of oligarchies. In all cases the interest promoted is that of the ruling group, not that of the people as a whole. However, if the people as a whole are put in charge, they will promote the interests of the people as a whole. Seeking their own interests, they will produce general happiness. Hence both premises are satisfied simultaneously.

It is perhaps unsurprising that the greatest happiness of the greatest number results if the majority (the greatest number) are put in charge. However the answer does depend upon certain presuppositions. It assumes that people act in their own interests. Even if this is what they generally intend to do (which might be disputed), it does not follow from this that they are successful. For they may not know their interests. For example, it is often held that people discount the future too severely, so they prefer less important immediate interests to more important long-term interests. If this is so, then democratic decisions will lead to too short-term results, which are not even in the interests of those voting (see Needs and interests; Public interest).

A related point is that this model takes preferences as they are, without allowing them to be changed by the democratic process. Yet if people are ill informed about what is good for them, it would be better to operate on the preferences before counting votes. Democracy treats all votes equally. But people may not be equally informed about their interests. So the result may be that some interests are catered for better than others. Analogously, treating votes equally means that strongly held and weakly held views are considered of equal importance. Yet if the goal is to maximize utility, it may be wrong to follow the weakly held view of a majority rather than the strongly held view of a significant minority. If the utility of getting something is supposed to be roughly proportional to the strength of the desire for it, then it could be that the total of less people multiplied by a greater utility per person is higher than the total of more people multiplied by less utility per person.

6 Other consequences

The idea of utilitarianism as a mere preference-satisfying machine, in which antecedently given preferences are satisfied, has often been criticized. One alternative is to treat the values more objectively. Democracy can then be shown to be good in terms of these independently specified consequences. Such was the approach of J.S. Mill (1861) and more recent defenders such as William Nelson (1980). Democracy is justified as a form of education or development; it is taken to be a political system in which individuals are made to think for themselves and are therefore improved. Even if the decisions they make are not the best decisions, it is better for individuals if they try and take part in such decisions.

Another consequence which might justify democracy is the supposed promotion of dynamic economic activity; as opposed to the sluggish effects supposedly emanating from more centralized planning and control. Yet even if democracy does correlate with such beneficial economic circumstances, it is not clear that this by itself can be used as an argument for promoting democracy. Jon Elster (1986) identifies the questionable role of such arguments based on indirect effects. For it may be that these other effects only happen if people are attached to democracy for more direct reasons (such as thinking that it is a just form of government). If people were only to support democracy because they thought that it encouraged economic dynamism, then the democracy would not work, and so the economic dynamism would not follow either.

This relates to another familiar problem with starting from antecedent preferences and then taking democracy to be a sort of market mechanism in which these preferences are traded. If people only act through self-interest, trying to get their antecedently given preferences fulfilled, then it is not obvious why they should vote at all. For the advantages of voting will come to them if the others vote and their own vote seems to be merely a cost. At the national government level, it is exceedingly unlikely that any one vote will be decisive. So they would be better off not voting at all.

One answer to all of these problems is to dispense with the idea of democracy being a mechanism for satisfying antecedently given preferences. Instead of taking these as given, democracy should be held as a device in which people develop and discover their views about what is right. And, in thinking about what is right, they should think about what is right for the group as a whole, and not just themselves. People should therefore participate in a form of decision making in which they share their ideas, discuss together and, with luck, eventually reach general agreement.

The form of arguments people can use in such discussions is naturally constrained, as people seeking agreement should look as if they are appealing to general principles rather than merely appealing to self-interest. The condition of publicity (that is, of what can be said publicly) imposes constraints. If people think from the general point of view rather than in terms of their own individual interest, the forms of reasoning and the antecedent judgements will be different. Discussion rather than voting becomes the central feature of democracy, and it is important that people can meet and talk together before decisions are made.

These ideas promoting discussion and participation have several presuppositions. They presuppose that people will be better able to work out the truth (about what is good for the group) by working in groups rather than individually. This may be the case if they are all independently motivated by the same desire to discover the truth. It is less obviously the case if there are deep conflicts of interest (such as capital against labour; or country against town; or this world against the next). The supposition is that group discussion leads to more rationality; but in some circumstances group dynamics merely increase and inflame passion, so that people behave badly together in a way that they never would separately.

The values considered at the start of this discussion - namely, liberty and equality - now reappear; only now not as the consequence of democratic activity but as its prerequisites. For if discussion is to reach the right answer, it needs to start with roughly equal power between the discussants. Otherwise discussion will be forced in the interests of the stronger. Hence the idea that democracy needs circumstances of roughly equal wealth (held by Montesquieu and Rousseau). Hence the Marxist criticism that Western liberal democracy works on the fiction of an idealized equality when the real situation is one of greatly unequal economic power. Hence John Rawls' argument (1971) that political parties should be paid for by the state to avoid the economically powerful buying votes (see Rawls, J. §2). Hence also the objections of feminist theorists. If men and women are antecedently in a

situation of different power, then the supposed equality of democracy will only result in most of the power remaining with the men. Discussion, yes: but only if the forum is subject to powerful antecedent control and regulation. Otherwise we return to the bad old world of bargaining between antecedently given preferences from which this optimistic espousal of discussion was meant to save us.

Democritus (mid 5th-4th century BC)

A co-founder with Leucippus of the theory of atomism, The Greek Philosopher Democritus developed it into a universal system, embracing physics, cosmology, epistemology, psychology and theology. He is also reported to have written on a wide range of topics, including mathematics, ethics, literary criticism and theory of language. His works are lost, except for a substantial number of quotations, mostly on ethics, whose authenticity is disputed. Our knowledge of his principal doctrines depends primarily on Aristotle's critical discussions, and secondarily on reports by historians of philosophy whose work derives from that of Aristotle and his school.

The atomists attempted to reconcile the observable data of plurality, motion and change with Parmenides' denial of the possibility of coming to be or ceasing to be. They postulated an infinite number of unchangeable primary substances, characterized by a minimum range of explanatory properties (shape, size, spatial ordering and orientation within a given arrangement). All observable bodies are aggregates of these basic substances, and what appears as generation and corruption is in fact the formation and dissolution of these aggregates. The basic substances are physically indivisible (whence the term atomon*, literally 'uncuttable') not merely in fact but in principle; (1) because (as Democritus argued) if it were theoretically possible to divide a material thing* ad infinitum*, the division would reduce the thing to nothing; and (2) because physical division presupposes that the thing divided contains gaps. Atoms are in eternal motion in empty space, the motion caused by an infinite series of prior atomic 'collisions'. (There is reason to believe, however, although the point is disputed, that atoms cannot collide, since they must always be separated by void, however small; hence impact is only apparent, and all action is at a distance.) The void is necessary for motion, but is characterized as 'what*-is-*not', thus violating the Eleatic principle that what-is-not cannot be.*

Democritus seems to have been the first thinker to recognize the observer-dependence of the secondary qualities. He argued from the distinction between appearance and reality to the unreliability of the senses, but it is disputed whether he embraced scepticism, or maintained that theory could make good the deficiency of the senses. He maintained a materialistic account of the mind, explaining thought and perception by the physical impact of images emitted by external objects. This theory gave rise to a naturalistic theology; he held that the gods are a special kind of images, endowed with life and intelligence, intervening in human affairs. The ethical fragments (if genuine) show that he maintained a conservative social philosophy on the basis of a form of enlightened hedonism.

1 Life and works

Democritus lived from approximately the middle of the fifth century BC to well into the following century. Though he was a co-founder of atomism with Leucippus, the exact relation between the two is obscure; Aristotle and his school agree in treating Leucippus as the originator of the theory, but also in assigning its basic principles to both, while later sources treat the theory as the work of Democritus alone. He may have collaborated with Leucippus, and almost certainly developed the latter's theory into a universal system.

Very little is known about Democritus' life. He came from Abdera, on the north coast of the Aegean (also the native city of Protagoras). He describes himself as being young in the old age of Anaxagoras, that is, probably in the 430s BC, and was traditionally reported to have lived to a very great age. He is said to have visited Athens and to have had some slight acquaintance with Socrates. The list of his works preserved by the third-century AD biographer Diogenes Laertius is long and encyclopedic in scope, including a complete account of the physical universe, the *Lesser World-System* (so called to distinguish it from his predecessor Leucippus' *Great World-System*), and works on astronomy and other natural sciences, epistemology, ethics, mathematics and literature. None survives. Ancient sources preserve almost 300 purported quotations, the great majority on ethics, from two different, although overlapping, collections of ethical maxims, one by the fifth-century anthologist Stobaeus, the other from a collection, probably earlier than that of Stobaeus, traditionally known as 'The Sayings of Democrates'. The authenticity of the ethical fragments is disputed. Sextus Empiricus preserves some important quotations on epistemology, and Plutarch, Galen and others preserve a few other miscellaneous quotations. For our knowledge of the physical doctrines we are reliant on the doxographical tradition stemming ultimately from Aristotle, who discusses atomism extensively (see doxography).

2 Physical doctrines

According to Aristotle, the atomists attempted to reconcile the observable data of plurality, motion and change with the Eleatic denial of the possibility of coming to be or ceasing to be. Accordingly they postulated unchangeable primary substances, and explained apparent generation and corruption as the formation and dissolution of aggregates of those substances. Since the theory had to account for an assumed infinity of phenomena, it assumed an infinite number of primary substances, while postulating the minimum range of explanatory properties, specifically shape, size, spatial ordering and orientation within a given arrangement. All observable bodies are aggregates of basic substances, which must therefore be too small to be perceived. These corpuscles are physically indivisible (*atomon*, literally 'uncuttable'), not merely in fact but in principle; Aristotle reports an (unsound) atomistic argument, which has some affinities with one of Zeno of Elea's arguments against plurality, that if (as Anaxagoras maintained) it were theoretically possible to divide a material thing *ad infinitum*, the division must reduce the thing to nothing (see Zeno of Elea §4; Anaxagoras §2). This Zenonian argument was supported by another for the same conclusion; atoms are theoretically indivisible because they contain no void. On this view, bodies split along their interstices; hence, where there are no interstices, as in an atom, no splitting is possible. (The same principle accounts for the immunity of the atoms to other kinds of change, such as reshaping, compression and expansion; all require displacement of matter within an atom, which is impossible without any gaps to receive the displaced matter.) It is tempting to connect the assumption that bodies split only along their interstices with the Principle of Sufficient Reason, which the atomists appealed to as a fundamental principle of explanation (arguing, for example, that the number of atomic shapes must be infinite, because there is no more reason for an atom to have one shape than another (Simplicius, *On Aristotle's Physics* 28.9-10), and that there must be infinitely many worlds because there is no more reason for one to have been formed here than elsewhere. Given the total uniformity of an atom, they may have thought that there could be no reason why it should split at any point, or in any direction, rather than any other. Hence, by the Principle of Sufficient Reason, it could not split at all.

Atoms are in a state of eternal motion in empty space; the motion is not the product of design, but is determined by an infinite series of prior atomic collisions (whence two of Aristotle's principle criticisms of Democritus: that he eliminated final causation and that he made all atomic motion 'unnatural', that is to say, imposed by external force). Empty space was postulated as required for motion, but was characterized as 'what-is-not', thus violating the Eleatic principle that what-is-not cannot be. We have no evidence of how the atomists met the accusation of outright self-contradiction. As well as explaining the possibility of motion, the void was postulated to account for the observed plurality of things, since the atomists followed Parmenides (fr. 8.22-5) in maintaining that there could not be many things if there were no void to separate them (see Parmenides §6). The theoretical role of the void in accounting for the separation of atoms from one another has an interesting implication, recorded by Philoponus (*On Aristotle's On Physics* 494.19-25, *On Aristotle's On Generation and Corruption* 158.26-159.7). Since atoms are separated from one another by the void, they can never strictly speaking come into contact with one another. For if they did, even momentarily, there would be nothing separating them from one another. But then they would be as inseparable from one another as the inseparable parts of a single atom, whose indivisibility is attributed to the lack of void within it (see above); indeed, the two former atoms would now be parts of a single larger atom. But, the atomists held, it is impossible that two things should become one. Holding atomic fusion to be theoretically impossible, and taking it that any case of contact between atoms would be a case of fusion (since only the intervening void prevents fusion), they perhaps drew the conclusion that contact itself is theoretically impossible. Hence what appears to be impact is in fact action at an extremely short distance; rather than actually banging into one another, atoms have to be conceived as repelling one another by some sort of force transmitted through the void. Again, although no source directly attests this, the interlocking of atoms which is the fundamental principle of the formation of aggregates is not strictly speaking interlocking, since the principle of no contact between atoms forbids interlocking as much as impact. Just as impact has to be reconstrued as something like magnetic repulsion, so interlocking has to be reconstrued as quasi-magnetic attraction. If this suggestion is correct (and it is fair to point out that no ancient source other than Philoponus supports it), it is a striking fact that, whereas the post-Renaissance corpuscular philosophy which developed from Greek atomism tended to take the impossibility of action at a distance as an axiom, the original form of the theory contained the a priori thesis that all action is action at a distance, and consequently that impact, as far from giving us our most fundamental conception of physical interaction, is itself a mere appearance which disappears from the world when the description of reality is pursued with full rigour (see Blasius of Parma §4; Bruno, G. §5).

3 Epistemology and psychology

Democritus seems to have been the first philosopher to recognize the observer-dependence of the secondary qualities. Perception of the secondary qualities reveals merely how things seem to us (and these qualities are said to be merely *nomōi*, or 'convention'), as opposed to how they really (*eteēi*) are - aggregates of unobservable corpuscles. The perception of any secondary quality is a response, not to the properties of an individual atom, but to a physical stimulus constituted by a continuous bombardment of a series of arrays of atoms. Thus visual perception, including the perception of colour, is a response to the impact on the visual organs of a continuous succession of films of atoms (*eidōla*) flowing from the surface of the perceived object. For an object to be red, for example, is thus for it to emit films of atoms of such a nature that, when those films collide with an appropriately situated perceiver, the object will look red to that perceiver.

It is therefore a necessary consequence of the atomists' account of the secondary qualities not merely that secondary qualities are among the causally significant properties of the atoms, but, more strongly, that atoms have no secondary qualities. Colour, sound, taste and smell are qualities of aggregates, not of single atoms. To ascribe one of these qualities to a subject is to describe that subject as so structured as to prompt a certain sensory response in a certain kind of perceiver; and the structure in question as described in terms of the intrinsic properties (shape and size) and relational properties (arrangement and orientation) of its constituent atoms. The persuasiveness or otherwise of the account of the secondary qualities cannot be separated from that of the whole theory of perception of which it is part, and that in turn cannot be separated from the theory of human nature, and ultimately of the natural world as a whole. As presented by the atomists, the theory is entirely speculative, since it posits as explanatory entities microscopic structures of whose existence and nature there could be no experimental confirmation. Modern developments in sciences such as neurophysiology have revised our conceptions of the structures underlying perceptual phenomena to such an extent that modern accounts would have been unrecognizable to Leucippus or Democritus; but the basic intuitions of ancient atomism - that appearances are to be explained at the level of the internal structure of the perceiver and of the perceived object, and that the ideal of science is to incorporate the description of those structures within the scope of a unified and quantitatively precise theory of the nature of matter in general - have stood the test of time.

According to some sources, Democritus used the contrast between unobservable atomic structures and the appearances which they present to us to demonstrate the unreliability of the senses. He then faced the problem of the justification of his theory, which was founded on data provided by the senses; in a famous fragment quoted by Galen the senses say to the mind, 'Wretched mind, you get your evidence from us, and yet do you overthrow us? The overthrow is a fall for you' (fr. 125). It is disputed whether Democritus drew a sceptical conclusion, or whether his position was rather that, since there can be no ground for preferring one piece of sensory information to another, the task of theory is to provide an account of how all appearances are appropriate representations of an underlying unobservable reality (that is, all appearances are true, a thesis which Aristotle attributes to him, and which was later explicitly maintained by the Epicureans; see Epicureanism (§6)).

Democritus' uncompromising materialism extended to his psychology. Although there is some conflict in the sources, the best evidence is that he drew no distinction between the rational soul or mind and the non-rational soul or life principle, giving a single account of both as a physical structure of spherical atoms permeating the entire body. This theory of the identity of soul and mind extended beyond identity of physical structure to identity of function; Democritus explained thought, the activity of the rational soul, by the same process as that by which he explained perception, one of the activities of the sensitive or non-rational soul. Both are produced by the impact on the soul of extremely fine, fast-moving films of atoms (*eidōla*), constantly emitted in continuous streams by the surfaces of everything around us. This theory combines a causal account of both perception and thought with a crude pictorial view of thought. The paradigm case of perception is vision; seeing something and thinking of something alike consist in picturing the thing seen or thought of, and picturing consists in having a series of actual physical pictures of the thing impinge on one's soul. While this assimilation of thought and experience has some affinities with classical Empiricism, it differs in one crucial respect; whereas the basic doctrine of empiricism is that thought derives from experience, for Democritus thought is a form of experience, or, more precisely, the categories of thought and experience are insufficiently differentiated to allow one to be characterized as more fundamental than the other. Among other difficulties, this theory faces the problem of accounting for the distinction, central to Democritus' epistemology, between perception of the observable properties of atomic

aggregates and thought of the unobservable structure of those aggregates. We have no knowledge of how, if at all, Democritus attempted to deal with this problem.

4 Theology

Another disputed question is whether Democritus' materialistic account of the universe left any room for the divine. According to most of the ancient sources he believed that there are gods, which are living, intelligent, material beings (of a peculiar sort), playing a significant role in human affairs. They are atomic compounds, and like all such compounds they come to be and perish. They did not create the physical world (of which they are part), nor, although they are intelligent, do they organize or control it. They are as firmly part of the natural order as any other living beings. Specifically, Democritus believed the gods to be living *eidōla*, probably of gigantic size, possessing intelligence, moral character and interest in human affairs. While some sources suggest that these *eidōla* emanate from actual divine beings, the majority of sources agree that they are themselves the only divine beings which Democritus recognized. Some modern scholars (for example, Barnes 1982) interpret this as amounting to atheism, taking Democritus to have held that the gods are nothing more than the contents of human fantasy. But for Democritus *eidōla* are not intrinsically psychological; they are not contents of subjective states, but part of the objective world, causing psychological states through their impact on physical minds. In this case his theory must explain their source and their properties, notably their being alive. Since the gods were of human form, it is plausible to suggest that their source is actual human beings, possibly giants living in the remote past. They are themselves alive in that, flowing from beings permeated with soul-atoms, they contain soul-atoms themselves. Consistently with this naturalistic theology Democritus gave a naturalistic account of the origin of religion, identifying two types of phenomena as having given rise to religious belief: first, the occurrence of *eidōla* themselves, presumably in dreams and ecstatic states; and second, celestial phenomena such as thunder, lightning and eclipses.

Democritus' theology thus contrives to incorporate some of the most characteristic features of the gods of traditional belief, notably their anthropomorphism, power, longevity (although not, crucially, immortality), personal interaction with humans and interest (for good or ill) in human affairs, within the framework of a naturalistic and materialistic theory. It is thus, despite the bold originality of its account of the divine nature, notably more conservative than some of its predecessors (especially the non-anthropomorphic monotheism normally attributed to Xenophanes) and than that of its Epicurean successor, whose main concern is to exclude the gods from all concern with human affairs (see Xenophanes §3; Epicureanism §§8-9).

5 Ethics and politics

The evidence for Democritus' ethical views differs radically from that for the areas discussed above, since while the ethical doxography is meagre, our sources (see §1) preserve a large body of purported quotations on ethical topics. While the bulk of this material is probably Democritean in origin, the existing quotations represent a long process of excerpting and paraphrase, making it difficult to determine how close any particular saying is to Democritus' own words. Various features of style and content suggest that Stobaeus' collection of maxims contains a greater proportion of authentically Democritean material than does the collection which passes under the name of 'Democrates'.

Subject to the limitations imposed by the nature of this material, we can draw some tentative conclusions about Democritus' ethical views. He was engaged with the wide-ranging contemporary debates on individual and social ethics of which we have evidence from Plato and other sources. On what Socrates presents as the fundamental question in ethics, 'How should one live?' (Plato, *Gorgias* 500c, *Republic* 352d), Democritus is the earliest thinker reported as having explicitly posited a supreme good or goal, which he called 'cheerfulness' or 'wellbeing', and which he appears to have identified with the untroubled enjoyment of life. It is reasonable to suppose that he shared the presumption of the primacy of self-interest which is common both to the Platonic Socrates (§6) and to his immoralist opponents, Callicles and Thrasymachus. Having identified the ultimate human interest with 'cheerfulness', the evidence of the testimonia and the fragments is that he thought that it was to be achieved by moderation, including moderation in the pursuit of pleasures, by discrimination of useful from harmful pleasures and by conformity to conventional morality. The upshot is a recommendation to a life of moderate, enlightened hedonism, which has some affinities with the life recommended by Socrates (whether in his own person or as representing ordinary enlightened views is disputed) in Plato's *Protagoras*), and, more obviously, with the

Epicurean ideal of which it was the forerunner.

An interesting feature of the fragments is the frequent stress on individual conscience. Some fragments stress the pleasures of a good conscience and the torments of a bad one (frs 174, 215) while others recommend that one should be motivated by one's internal sense of shame rather than by concern for the opinion of others (frs 244, 264, 'Sayings of Democrates' 84). This theme may well reflect the interest, discernible in contemporary debates, in what later came to be known as the question of the sanctions of morality. A recurrent theme in criticisms of conventional morality was that, since the enforcement of morality rests on conventions, someone who can escape conventional sanctions, for example by doing wrong in secret, has no reason to comply with moral demands. Proponents of such a belief include Antiphon (fr. 44), Critias (fr. 25) (see Physis and nomos) and Plato, in Glaucon's tale of Gyges' ring in the *Republic* (359b-360d). A defender of conventional morality who, like Democritus and Plato, accepts the primacy of self-interest therefore faces the challenge of showing, in one way or another, that self-interest is best promoted by the observance of conventional moral precepts.

The appeal to divine sanctions, cynically described in Critias' fragment 25, represents one way of doing this, and there are some traces of the same response in Democritus. While his theory of the atomic, and hence mortal, nature of the soul admits no possibility of postmortem rewards and punishments, the theory allows for divine rewards and punishments in this life. Fragment 175 suggests a complication: the gods bestow benefits on humans, but humans bring harm on themselves through their own folly. Is the thought that the gods do not inflict punishment arbitrarily, but that humans bring it on themselves? Or is it rather that the form which divine punishments take is that of natural calamities, which humans fail to avoid through their own folly? The latter alternative would make the pangs of conscience one of the forms of divine punishment, while the former would see it as a further sanction. Either way (and the question is surely unanswerable), we have some evidence that Democritus was the earliest thinker to make the appeal to 'internal sanctions' central to his attempt to derive morality from self-interest, thus opening up a path followed by others including Bishop Butler (§§2-4) and John Stuart Mill (§11).

The attempt, however pursued, to ground morality in self-interest involves the rejection of the antithesis between law or convention (*nomos*) and nature (*physis*) which underlies much criticism of morality in the fifth and fourth centuries BC (see Physis and nomos). For Antiphon, Callicles, Thrasymachus and Glaucon, nature prompts one to seek one's own interest while law and convention seek, more or less successfully, to inhibit one from doing so. But if one's long-term interest is the attainment of a pleasant life, and if the natural consequences of wrong-doing, including ill health, insecurity and the pangs of conscience, give one an unpleasant life, while the natural consequences of right-doing give one a contrastingly pleasant life, then nature and convention point in the same direction, not in opposite directions as the critics of morality allege. (We have no evidence whether Democritus had considered the objections that conscience is a product of convention, and that exhorting people to develop their conscience assumes that it must be.) Although the texts contain no express mention of the *nomos*/*physis* contrast itself, several of them refer to law in such a way as to suggest rejection of the antithesis. Fragment 248 asserts that the aim of law is to benefit people, thus contradicting Glaucon's claim (Plato, *Republic* II 359c) that law constrains people contrary to their natural bent. Fragment 248 is supplemented and explained by fragment 245: laws interfere with people living as they please in order only to stop them from harming one another, to which they are prompted by envy. So law frees people from the aggression of others, thus benefiting them by giving them the opportunity to follow the promptings of nature towards their own advantage. The strongest expression of the integration of *nomos* and *physis* is found in fragment 252: the city's being well run is the greatest good, and if it is preserved everything is preserved, while if it is destroyed everything is destroyed. That is to say, a stable community is necessary for the attainment of that wellbeing which is nature's goal for us. This quotation encapsulates the central point in the defence of *nomos* (emphasized in Protagoras' myth at (Plato, *Protagoras* 322a-323a) that law and civilization are not contrary to nature, but required for human nature to flourish, a point also central to the Epicurean account of the development of civilization.

Demonstratives and indexicals

Demonstratives and indexicals are words and phrases whose interpretations are dependent on features of the context in which they are used. For example, the reference of 'I' depends on conditions associated with its use: as you use it, it refers to you; as I use it, it refers to me. In contrast, what 'the inventor of bifocals' refers to does not depend on when or where or by whom it is used. Among indexicals are the words 'here', 'now', 'today', demonstrative pronouns such as 'this', reflexive, possessive and personal pronouns; and compound phrases employing indexicals, such as 'my mother'. C.S. Peirce introduced the term 'indexical' to suggest the idea of pointing (as in 'index finger').

The phenomenon of indexicality figures prominently in recent debates in philosophy. This is because indexicals allow us to express beliefs about our subjective 'place' in the world, beliefs which are the immediate antecedents of action; and some argue that such beliefs are irreducibly indexical. For example, my belief that I am about to be attacked by a bear is distinct from my belief that HD is about to be attacked by a bear, since my having the former belief explains why I act as I do (I flee), whereas my having the latter belief explains nothing unless the explanation continues 'and I believe that I am HD'. It seems impossible to describe the beliefs that prompt my action without the help of 'I'. Similarly, some have argued that indexical-free accounts of the self or of consciousness are necessarily incomplete, so that a purely objective physicalism is impossible. In a different vein, some (such as Putnam 1975) have argued that our terms for natural substances, kinds and phenomena ('gold', 'water', 'light') are indexical in a way that entails that certain substantive scientific claims - for example, that water is H_2O - are, if true, necessarily true. Thus, reflection on indexicality has yielded some surprising (and controversial) philosophical conclusions.

1 Semantic data

An indexical is context-dependent: its interpretation varies with changes in aspects of the context of use. Yet almost any expression exhibits variation in interpretation with respect to some parameter or other. For example, a contingent sentence is one which is possibly true and possibly false, so we may think of it as varying in truth-value with changes in possible worlds. But mere contingency is not a species of indexicality. Similarly, tensed verbs induce variation in interpretation with respect to the passage of time, but tense is not usually viewed by linguists and logicians as a kind of indexicality (although there is some confusion about the matter). The difference between true context dependence and mere 'parameter dependence' can be seen as follows. Consider the sentence

(1) Jones will remember what Smith said just now.

The truth or falsity of this sentence at a moment in time *t* depends on the truth or falsity of the present tense sentence

(2) Jones remembers what Smith said just now

at moments t' future to *t*. But the referent of the occurrence of 'now' in (2) must refer back to *t* and not to any of the future moments t'. This means that the semantic rule for 'now' cannot be simply the rule which states that at any time *t*, 'now' refers to *t*. Instead, the rule must say that a use of 'now' at a time *t* will refer at time *t and at any other time* to *t*. Thus, the rule for 'now' must be 'double-indexed'. In general, the semantic rules for indexicals must involve the pairing of two sorts of parameter: contextual and circumstantial. The contextual parameters (speaker, time of utterance, place of utterance, world of utterance, addressee and so on) fix the referent of an indexical, so that its interpretation is unaffected by any circumstantial parameter (possible world, moment of time) required by the presence of tense or modal elements. Hereafter, the phrase 'context-dependent' will refer to the dependence of indexicals on both context and circumstance.

Indexicals are 'referential' in that they invariably have wide scope when embedded in tensed, modal or propositional attitude constructions. For example, consider the two statements 'The mayor might not have been a Democrat' and 'That person over there, the Mayor, might not have been a Democrat'. The former statement could be interpreted to mean merely that the office of mayor might have been occupied by a non-Democrat; but the latter statement can only be interpreted to mean that a certain person (who happens to be the mayor) might not have been

a Democrat. This property of indexicals is an effect of their context dependence. The referent of the indexical phrase ‘that person’ is fixed by the context and not by circumstances required to interpret the modal element ‘might have been’.

Though the interpretation of an indexical will vary with the context, indexicals are not in general ambiguous. Your use of ‘I’ and mine are linked by a common meaning. The language supplies a rule - the same rule for both of us - for the use of ‘I’. The rule is roughly this: ‘As *x* uses "I" in such and such a context, "I" refers to *x* in all circumstances’. But this sort of meaning is not like the Fregean sense of a definite description or proper name; it is not a concept of some fixed object and it cannot be combined with the sense of a (non-indexical) predicate to yield a complete proposition (see Frege, G. §§2-3). Some theorists believe that this fact requires the introduction into semantics of a whole new level of meaning distinct from both sense and reference. Kaplan, for example, draws a three-way distinction between the ‘character’ (linguistic meaning), content (roughly, sense) and referent of an indexical expression such as ‘my mother’ (1970). Kaplan’s view may not be inevitable, however. It may be that ‘I’ has an ‘incomplete sense’, in the way that the sense of a functional expression ‘the square root of *x*’ or ‘the author of *x*’ is incomplete. If so, that would explain why the linguistic meaning of ‘I’ cannot be combined with a predicate to yield a complete proposition and there would be no need to postulate a kind of meaning in addition to sense and reference.

Some subscribe to the principle that for one to understand an ‘object-dependent’ proposition - a proposition that such and such an object has such and such a property - one must be able to identify the object in question; one must be able to say who or what it is. This principle seems to be directly contradicted by propositions involving indexicals. I can know that I am hungry or that it is raining now without having any substantive information about who I am or what time it is. Similarly, if I point to something and say ‘I don’t have the slightest idea what that is’ I might well speak the truth! Yet these propositions are object-dependent in that they would not be available if the objects they are about did not exist. Let us mark the fact that speakers can use indexicals with total understanding without having any substantive knowledge of their referents by saying that indexicals are ‘transparent’.

Some indexical sentences have the property of being true in any context of use. For example, one who says (or thinks) ‘I exist’ or ‘I am here now’ or ‘I am saying (or thinking) something now’ must be right. These sentences, then, are somewhat similar to logical truths. But if I say ‘I exist’, then what I say (that HD exists) is not a *necessary* truth, for there are possible circumstances in which I do not exist. So a sentence such as ‘I exist’ is contingent in one respect and yet non-contingent in another. Any theory of indexicality must explain how this is possible.

Perhaps the most puzzling aspect of indexicals is that some of them seem to be ineliminable and their ineliminability seems to have to do with the baffling distinction between subjectivity and objectivity (see Content, indexical). Perry gives the following example (1979). Suppose a meeting is set for Tuesday at noon. All week you believe that the meeting will start at noon on Tuesday. At a certain point, you leave to go to the meeting. Obviously, you must have acquired some new information, a new belief, distinct from the belief that the meeting starts at noon on Tuesday, for you now act in a way you have not acted all week (that is, you leave to go to the meeting). What belief is this? It is the belief that the meeting starts *now*, or, more elaborately, the belief that the meeting starts at noon on Tuesday and it is *now* noon on Tuesday. The use of ‘now’ in describing your new belief seems essential, and not eliminable in favour of non-indexical designations of noon on Tuesday. Moreover, your new ‘indexical belief’ places you within the fabric of time in a way that the beliefs you acquire when you look at your appointment book to determine the time of the meeting do not. An observer ‘outside of time’ could have the belief that the meeting starts at noon on Tuesday, but not the belief that the meeting starts ‘now’. In this way, your indexical belief seems linked to your subjective place in the world. Perry calls such beliefs ‘self-locating’ beliefs. Yet all this is quite puzzling. Is your belief that it is ‘now’ noon on Tuesday something that you can believe only ‘now’? Certainly, you can believe truly that it is now noon on Tuesday only at noon on Tuesday. But can you not at a later time continue to hold precisely the belief you expressed earlier by saying ‘It is now noon on Tuesday’? Yet if you believe at the later time exactly what you believed at the earlier, then why do you not, at the later time, do just what you did at the earlier time - namely, head off to the meeting? Similarly, I believe that I am HD. Can you not believe that too? If you believe just what I do when I believe that I am HD - that is, if you believe exactly the proposition I do, it would appear to follow that our mental states *vis-à-vis* this belief must be identical, then why do you not have any inclination, as I do, to identify yourself as HD? Let us call this ‘the puzzle about

indexical belief'. The puzzle has two parts: first, one argues on the basis of behavioural changes (for example, your getting up to go to the meeting) that an indexical belief (assertion, thought) is not equivalent to any non-indexical counterpart of it. Second, however, similar behavioural changes - or the lack of any - seem to show that such beliefs are 'isolated' - that they cannot be retained over time or shared by different persons: only I can know that I am HD, and that seems counterintuitive. Any adequate theory of indexicality must solve this puzzle about indexical belief.

2 The Kaplan-Perry theory

The most influential theory that has had some success explaining the semantic data about indexicals as outlined above was developed by Kaplan in a series of papers originating in the late 1960s and early 1970s. In the mid-1970s, Perry applied Kaplan's theory to explain the data about the ineliminability of indexicality and the puzzle about indexical belief - data that were first noticed and systematically studied by Castañeda (1967).

According to Kaplan-Perry theory (KPT), each indexical expression has a 'character' or linguistic meaning (Perry's term is 'role') and, given a context, a 'content' in that context. The content in a context of a (declarative) sentence containing an indexical is a 'singular proposition' - a proposition containing the very referent of the indexical as a 'constituent' rather than a sense or concept of that referent. So the content of my use of 'I am hungry now' at a time *t* is a proposition to the effect that HD is hungry at time *t* - with HD right there 'in' the proposition, in at least a metaphorical sense. Kaplan takes the character of an indexical to be a function (in the mathematical sense) that takes context into content. Contexts are treated as *n*-tuples $c = \langle a, t, p, w, \ldots \rangle$ with coordinates for the 'agent of the context' (to handle 'I'), the 'time of the context' (to handle 'now'), the 'place of the context', the 'world of the context' and so on (for example, there should be a coordinate for the 'day of the context' to handle 'yesterday', 'today' and 'tomorrow'). To deal with pure demonstratives such as 'this', Kaplan adds a coordinate for a 'demonstration'. This is a kind of abstract counterpart of an act of pointing. For example, the sentence 'That is mine now' will be true at a parameter $\langle a, t, p, w, d, \ldots \rangle$ if the demonstrated object *d* belongs to agent *a* at *t* in place *p* and world *w*.

Kaplan distinguishes between 'contexts' and 'circumstances'. Formally, the latter are pairs $\langle t, w \rangle$ with *t* a time and *w* a possible world. Strictly, expressions are evaluated relative to parameters of the form $\langle \text{context}, \text{circumstance} \rangle$. So the semantic rules are double-indexed. In addition, Kaplan claims that indexicals are 'directly referential'. By this he means that an indexical refers without the aid of a Fregean sense. In this respect indexicals are like proper names. But proper names are, in Kaplan's view, unlike indexicals in that the latter possess characters whereas the former do not (see Proper names §§2-3).

By appealing to the content/character and context/circumstance distinctions, KPT can readily explain the fact that indexicals are context-dependent, referential and univocal. Moreover, the character/content distinction helps to explain the transparency of indexicals. One need only grasp the character of an indexical to use it with understanding. On occasion, its content may be hidden, as in the case of amnesiacs, who, despite their affliction, can certainly use the first person pronoun perfectly competently. KPT can also explain the special status of sentences such as 'I exist'. The character of 'I exist' always produces a true content in any context. But that content may turn out to be false in further circumstances. For example, if you now write 'I exist' in your diary, the content you express is true now. But, inevitably, that content will be false years hence in circumstances in which you no longer exist and someone then reads these words in your diary. According to KPT, 'I exist' is a logical truth, although its necessitation, 'Necessarily, I exist', and its temporal necessitation, 'It is always the case that I exist', are not. KPT thus involves a novel conception of logical truth. For it is usually assumed that the class of logical truths contains 'Necessarily, *P*' and 'It is always the case that *P*' if it contains *P*. Finally, KPT solves the problem of indexical belief by appealing to the notion of character. KPT holds that belief is linked to action via character, not content. If you and I have beliefs with the same content but different character we may well behave differently. But if we have beliefs with the same character and different content we may well behave in the same way. When each of us thinks 'I am about to be attacked by a bear' (same character, different content) we both run for our lives, but when I think 'I am about to be attacked by a bear' and you think 'You are about to be attacked by a bear' (same content, different character) I run for my life and you do not. Similarly, you can retain the belief that the meeting starts now but you can express it at a later time only by using words having a character distinct from that of 'The meeting starts now', and it is the difference in character that accounts for the fact that, at the later

time, you do not do what you did at the earlier time. Likewise, KPT appeals to character to account for the difference between the thought that I am about to be attacked by a bear and the thought that HD is about to be attacked by a bear. The former has a certain character which the latter does not, and that makes all the difference. Similarly, consider the difference between the thought that I am HD and that HD is HD. The former is informative whereas the latter is not. Again, the difference can be traced to the fact that 'I' has a certain character which 'HD' does not.

KPT needs only the character/content and context/circumstance distinctions to account for the semantic data. But it goes further in claiming that indexicals are 'directly referential' and that indexicals give rise to 'singular propositions'. Proponents of KPT argue in several ways for the direct reference thesis. First, Kaplan argues that 'I' does not have the sense of 'the speaker' or any description such as 'the utterer' or 'the thinker'. He would argue, for example, that since 'I am not the speaker' is not contradictory, whereas 'The speaker is not the speaker' is contradictory, 'I' and 'the speaker' are not synonymous. But this argument seems equivocal. Any candidate synonym for 'I' must be context-dependent (and not just parameter-dependent). If we associate a context-dependent rule with 'the speaker' - so that it refers in any circumstance to the 'speaker of the context' - then 'I am not the speaker' is indeed contradictory. It is only by treating 'I' as context-dependent and 'the speaker' as merely parameter-dependent (as it is in one sense) that there is a discrepancy. Second, Kaplan argues in the following way. The descriptive meaning of 'now' is given by the following rule: at *t*, 'now' refers to *t*. Thus, the descriptive meaning of 'now' is 'either inapplicable or irrelevant to determining a referent with respect to a circumstance of evaluation' (1989: 500). Hence, 'now' is directly referential - its descriptive meaning does not serve as the route to its referent in a circumstance. This argument does not work either. One can take the view, as explained above, that the descriptive rule for 'now' is not the one Kaplan assumes. (So the first premise of Kaplan's argument is false.) And if we substitute the double-indexed rule for 'now' it cannot be argued that descriptive meaning (that is, the double-indexed rule) of 'now' is 'irrelevant or inapplicable' to determining its referent in a circumstance.

Dennett, Daniel Clement (1942-)

A student of Gilbert Ryle and a connoisseur of cognitive psychology, neuroscience and evolutionary biology, American philosopher Daniel Dennett has urged Rylean views in the philosophy of mind, especially on each title topic of his first book,Content and Consciousness (1969). He defends a broadly instrumentalist view of propositional attitudes (such as belief and desire) and their intentional contents; like Ryle and the behaviourists, Dennett rejects the idea of beliefs and desires as causally active inner states of people. Construing them in a more purely operational or instrumental fashion, he maintains instead that belief- and desire-ascriptions are merely caculational devices.

Dennett offers a severely deflationary account of consciousness, subjectivity and the phenomenal or qualitative character of sensory states. He maintains that those topics are conceptually posterior to that of propositional-attitude content: the qualitative features of which we are directly conscious in experience are merely the intentional contents of judgments.

1 Propositional attitudes

Rejecting the idea of beliefs and desires as inner causes, Dennett maintains instead that ascriptions of belief and desire are merely calculational devices, that happen to have predictive usefulness (see Ryle, G.; Behaviourism, analytic). In interpreting other creatures, which is something we do constantly without knowing a thing about those creatures' insides, we start by trusting that they will believe what they should believe given their perceptions and desire what they should desire given their needs; then we correct empirically for observed departures from those normative ideals. Such ascriptions are often objectively true, he grants, but not in virtue of describing inner mechanisms, any more than references to centres of gravity, kinematic vectors and the Equator describe inner mechanisms.

Thus Dennett is an instrumentalist of sorts about propositional attitudes, such as belief and desire. To ascribe a 'belief' or a 'desire' is not to describe some segment of physical reality, Dennett says, but is more like performing part of a calculation. But he also protests that his own interpretation-based view does not rob his propositional-attitude concepts of their objectivity, for he understands the truth of an attitude ascription as being determined by whether someone's taking a certain interpretive stance *would in fact* achieve good predictive results. Still, for Dennett, attitude content is conceptually constructed out of purpose-relative interpretation; his objectivity does not amount to determinacy (he explicitly endorses Quine's indeterminacy thesis for content); and for him, a thing's innards (including the matter of whether it has any) are conceptually irrelevant to its having intentional states.

Dennett has always used mathematical abstractions, such as centres of gravity, to illustrate the sort of view he favours. It should be noted, however, that he has recently used this comparison to moderate his line. In an important paper, 'Real Patterns' (1991a), he emphasizes the reality of mathematical abstractions and de-emphasizes interpretation.

Dennett offers five grounds for his rejection of the common-sensical inner-cause thesis. (1) He thinks it ludicrously unlikely that any science will ever turn up any distinctive inner-causal mechanism that would be shared by all the possible subjects that had a particular belief. (2) He offers numerous objections to 'language-of-thought psychology', the most popular inner-cause theory (see Language of thought). (3) He compares the belief/desire interpretation of human beings to that of lower animals, chess-playing computers and even lightning rods, arguing that in their case we have no reason to think of belief- and desire-ascriptions as other than mere calculational or predictive devices, and then that we have no more reason for the case of humans to think of belief- and desire-ascriptions as other than such devices. (4) Dennett argues that the verification conditions of belief- and desire-ascriptions are basically a matter of extrapolating rationally from what subjects ought to believe and want in their circumstances, and then he boldly identifies the truth-makers of those ascriptions with these verification conditions, challenging inner-cause theorists to show why instrumentalism does not accommodate all the actual evidence. (5) He argues that in any case if a purely normative assumption (the 'rationality assumption', that people will generally believe what they ought to believe and desire what they should desire) is required for the licensing of an ascription, then the ascription cannot itself be a purely factual description of a plain state of affairs (see

Propositional attitudes).

2 Freedom of the will

In *Elbow Room* (1984) Dennett defends a common-sensical compatibilism regarding free will and determinism against attacks by metaphysicians and also against other common-sensical 'intuitions' that he takes to be confused. Here his style as well as his substance is Rylean: he does not engage serious contemporary incompatibilist arguments, but only jollies the reader into thinking that such arguments must be misguided. However, he does offer positive compatibilist accounts of practical reason, control over one's actions, deliberation and the appropriateness of holding people responsible (see Free will).

3 Consciousness

Dennett's mature view of consciousness and related topics is expounded at length in *Consciousness Explained* (1991b). His main claims are that there is nothing to the human mind that is not already constituted by the brain; that the brain itself is but a bag of tricks, an only very loose improvised association of little specialists whose individual actions contribute piecemeal and somewhat haphazardly to a subject's operative psychological state; that linguistic utterances do not normally express determinate pre-existing thought contents; and that there is no single 'whole me', or self or Boss Unit or even CPU within the brain, serving as chief executive of my utterings and other actions (see Consciousness).

Dennett is especially concerned to deny that there is any determinate stage of information processing that is the locus of conscious mental states or events; there is no such locus at all, however physically characterized. He calls his target 'Cartesian materialism', that being the usually tacit assumption that there is a physically realized spatial or temporal turnstile in the brain, a stage where 'it all comes together' and the product of pre-processing is exhibited 'to consciousness'.

Dennett gives two arguments against Cartesian materialism. First, given his naturalism about brains and the unplanned nature of their organization, it is unlikely that nature has furnished the human brain with any central viewing-room or single monitor to do the viewing; nor is there any positive neurophysiological sign of such organs. Second, Dennett adverts to the famous 'temporal anomalies' of consciousness discovered by psychophysical research, such as color phi, the cutaneous rabbit and Libet's 'backward referral' of sensory experiences, in which, for example, the mind seems to detect a stimulus before that stimulus could possibly have been processed by the brain. Dennett argues at length that those curious phenomena are anomalous only as long as Cartesian materialism is being assumed; jettison the assumption, and the phenomena are readily explained.

Dennett's recommended alternative to Cartesian materialism is the 'Multiple Drafts' model:

> What we actually experience is a product of many processes of interpretation - editorial processes, in effect. They take in relatively raw and one-sided representations, and yield collated, revised, enhanced representations, and they take place in the streams of activity occurring in various parts of the brain.…Once a particular 'observation' of some feature has been made, by a specialized, localized portion of the brain, the information content thus fixed does not have to be sent somewhere else to be rediscriminated by some 'master' discriminator.
>
> (1991b: 112-13)

The resulting stream of contents, subject to continual editing by many processes distributed around in the brain, is not altogether like a narrative, because of its multiplicity; at any point in time there are 'multiple drafts' of narrative fragments at various stages of editing in various places in the brain.

Dennett grants that there is something of the sort often called 'the stream of consciousness': 'Conscious human minds are more-or-less serial virtual machines implemented - inefficiently - on the parallel hardware that evolution has provided for us' (1991b: 218). They are 'Joycean' virtual machines that formulate synthesized reports of their own passing states, though the reports are almost never entirely accurate.

By way of *explaining* consciousness as advertised, Dennett offers a 'method for phenomenology', called 'heterophenomenology'. He says the method is designed to 'do justice to the most private and ineffable subjective experiences, while never abandoning the methodological scruples of science' (1991b: 72). It is to listen carefully

to a subject's introspective reports, respect them as perfectly sincere, and take them as serious descriptions of the subject's 'heterophenomenological world'. That world will be 'a stable, intersubjectively confirmable theoretical posit' (1991b: 81). But the cognitive scientist is to take the subject's narrative as fiction, or, less pejoratively, as a narrative that may or may not be true, just as an anthropologist takes the narratives of a primitive people. The job of the psychologist is then to discover whatever it is in the brain's great chaos of information processing that makes subjects produce the narratives that they do. To make that discovery is, in one sense, to explain the subject's consciousness.

Some readers have insisted that Dennett has simply avoided the real issues. If all the scientist need do is explain propositional sayings in terms of internal propositional states and episodes, then we know already that neither the scientist nor Dennett will find or even seek anything about phenomenal character, subjectivity, qualia, or any other feature of consciousness that makes it interesting over and above bare intentionality or aboutness *per se*. It may seem that Dennett has simply changed the subject. But he does squarely address the questions of subjectivity and phenomenal character in particular. He rejects the thesis of Thomas Nagel and Frank Jackson that an omniscient objective science would necessarily leave the introspectible first-person aspects of sensory experiences unexplained and even unrecorded, and he treats phenomenal properties of sensations essentially as representational contents, properties ascribed truly or falsely to external objects or to parts of one's own body (see Qualia).

Denys the Carthusian (1402/3-71)

Denys de Leeuwis was born in the village of Rijkel, in modern Belgium. In 1421 he matriculated at the University of Cologne, where he received the Master of Arts degree in 1424. There he followed 'the way of Thomas Aquinas', whom he calls his 'patron' in his early works. Later Denys adopted 'Albertist' against 'Thomist' positions on a number of philosophical issues. After leaving the University, he entered the Carthusian monastery in Roermond, where, save for brief periods, he spent the rest of his life. He corresponded with Nicholas of Cusa and dedicated two or three works to him. Denys was a voracious reader of the ancient and medieval philosophers whose writings were available in Latin, and of scholastic theologians. Because of his extensive references to authorities, historians often call him 'eclectic'. Yet from his sources he educes his own distinctive philosophy. Like Albert the Great, Denys practised philosophy and theology by paraphrasing and analysing their histories.

Denys was one of the most prolific writers of the Middle Ages. His writings include scholastic, mystical, moral and pastoral commentaries and treatises, commentaries on each book of Scripture, over 900 sermons, and paraphrase/commentaries on works by Aquinas. His major philosophical works are *De lumine christianae theoriae (The Light of Christian Theory)*, encyclopedic commentaries on Peter Lombard's *Sentences* (see Lombard, P.) *compendia* of philosophy and theology that distill materials from his commentaries on the *Sentences* and summarize his own positions, a commentary on Boethius' *Consolation of Philosophy* (see Boethius, A.M.S.) and commentaries on all of the writings of Pseudo-Dionysius. In Book I of *De lumine*, Denys analyses the teaching of many 'Peripatetic' and 'Platonic' philosophers on a wide range of metaphysical questions. Likewise, on each question of the *Sentences* he reports and interprets the teaching of many scholastic doctors. He discounts the arguments of 'nominalists' as more concerned with 'terms' than 'realities', returning instead to the teachings of thirteenth-century masters.

Like many fifteenth-century philosophers, Denys was preoccupied with the question of the soul's immortality. Influenced especially by Avicenna (see Ibn Sina) and Albert the Great, he maintains that the immortality of the soul can be demonstrated by reason alone (see Soul, nature and immortality of). In this context, he argues against Aquinas that the human mind need not have recourse to phantasms in every act of knowing and that it is capable of knowing separated substances. The mind's ability to know the essences of things without phantasms is the surest evidence of its immortality, and its natural capacity for pure abstraction is the foundation for the imageless contemplation of mystical theology.

Denys' understanding of the soul's self-subsistence and its ways of knowing affects other philosophic doctrines. He argues that the soul knows some first principles by immediate self-reference, and that the individuation of persons is not effected by matter alone, but by the whole human composite, most powerfully by its spiritual form. He disputes a 'real' distinction between essence and existence in creatures, arguing instead - in a way reminiscent of Henry of Ghent - for an 'intentional' distinction between them (see Existence). His noetic theory admits the possibility of a natural, philosophic beatitude, wherein the soul contemplates separated substances in the participated light of the lowest Intelligence in the hierarchy of celestial beings. In accord with these conclusions, Denys draws a sharp distinction between 'natural, philosophic wisdom' and 'supernatural, theological wisdom', which are analogically coordinated and touch at the points of God's existence, unity and attributes. True philosophical conclusions never contradict divine revelation. Here Denys' 'eclecticism' serves him well; among the philosophers he discovers those teachings most accordant with the 'analogy of faith', reconciles them among themselves, and brings them into rapport with the divinely revealed standard. Denys' departure from Thomistic conceptions was prompted by his reading of Pseudo-Dionysius, whom he considered to be the greatest authority of Christian wisdom.

Nevertheless, Denys retained many of the insights of Aristotle and Thomas Aquinas. He states that Aristotle's understanding of God as 'the pure act of being' is one of the most sublime of all philosophical teachings. He affirms that the intellectual soul is the single, substantial form of the human body, grants that human knowing ordinarily requires phantasms, and argues a 'real distinction' among the faculties of the soul. He maintains the priority of the intellect over the will in every human act, and teaches that love in the will is exactly commensurate to light in the intellect.

Denys conceived his philosophical enterprise as a remedy to attitudes common among his monastic brethren, who often scorned scholastic teaching and exalted the affections and the will in the spiritual life. Beyond that, he sought to reconcile the varying doctrines of the philosophers and the scholastic theologians by means of the higher, unified light of mystical theology.

KENT EMERY, JR

List of works

Denys the Carthusian (1402/3-71) *Opera omnia*; ed. monks of the Carthusian Order, *Doctoris ecstatici D. Dionysii Cartusiani Opera omnia*, Montreuil/Tournai/Parkminster: Typis Cartusiae S.M. de Pratis, 1896-1935, 42 vols.(Essentially a reprinting of sixteenth-century editions, with excellent indexes of names and topics.)

Denys the Carthusian (1440-5) *De contemplatione (On Contemplation)*; in *Opera omnia* 41: 133-289.(This is Denys' major work on contemplative theory and practice; it treats the different kinds of contemplation, recites the teaching of the most notable patristic and medieval masters, and resolves disputed questions concerning the nature of mystical union.)

Denys the Carthusian (*c*.1451) *De lumine christianae theoriae (The Light of Christian Theory)*; in *Opera omnia* 33: 233-513.(In the first book of this work, Denys recites and analyses philosophical doctrines about the 'going out' of all things from the first principle; in the second book, based largely on Aquinas' *Summa contra gentiles*, he treats the 'return' of human creatures to God through Christian grace and perfection.)

Denys the Carthusian (*c*.1464) *Commentaria in IV libros Sententiarum (Commentaries on the Four Books of the Sentences)*; in *Opera omnia* vols 19-25.(In these massive commentaries, Denys arranges dialectically, recites and comments upon or criticizes the opinions of many scholastic thinkers on each question of Peter Lombard's *Sentences*.)

Denys the Carthusian (*c*.1465) *Elementatio philosophica (Elements of Philosophy)*; in *Opera omnia* 33: 21-231.(This is an epitome of the strictly philosophic matters and questions extracted from the commentaries on the *Sentences* and arranged in a proper philosophical order.)

Denys the Carthusian (*c*.1465) *Elementatio theologica (Elements of Theology)*; in *Opera omnia* 33: 21-231.(In this work, Denys extracts from his commentaries on the *Sentences* strictly theological matters and questions and states his own conclusions.)

Denys the Carthusian (*c*.1466) *Ennarationes in V libros De consolatione philosophiae B. Severinii Boetii (Commentary on Boethius' Consolation of Philosophy)*; in *Opera omnia* vol. 26.(In this work, cast in the form of a dialogue between a master and a disciple, Denys gives a 'literal' philosophic commentary on Boethius' famous text, to which he joins 'allegorical', theological readings.)

Denys the Carthusian (1466-7) *Commentaria in libros S. Dionysii Areopagitae (Commentaries on the Writings of Dionysius the Areopagite)*; in *Opera omnia* vols 15-16.(With Albert the Great, Denys was the only Latin writer to comment on each work in the Dionysian corpus, including the letters; his commentaries are line-by-line, and include articles about disputed points of interpretation.)

Deontic logic

Deontic logic is the investigation of the logic of normative concepts, especially obligation ('ought', 'should', 'must'), permission ('may') and prohibition ('ought not', 'forbidden'). Deontic logic differs from normative legal theory and ethics in that it does not attempt to determine which principles hold, nor what obligations exist, for any given system. Rather it seeks to develop a formal language that can adequately represent the normative expressions of natural languages, and to regiment such expressions in a logical system.

The theorems of deontic logic specify relationships both among normative concepts (for example, whatever is obligatory is permissible) and between normative and non-normative concepts (for example, whatever is obligatory is possible). Contemporary research beginning with von Wright treats deontic logic as a branch of modal logic, in so far as (as was noted already by medieval logicians) the logical relations between the obligatory, permissible and forbidden to some extent parallel those between the necessary, possible and impossible (concepts treated in 'alethic' modal logic).

1 Standard deontic logic (SDL)

Deontic logic is the logic of normative reasoning. It is common in deontic logic to take one of the three concepts - 'obligatory', 'forbidden', 'permissible' - as primitive and to define the others in terms of the chosen one, the most popular approach defining the permissible and forbidden in terms of the obligatory. In 'standard deontic logic' (SDL) a modal operator *O* is added to the language of propositional logic so that if *p* is a sentence of the language, then so is *Op*, which informally expresses 'It is obligatory that *p*'. (Alternative approaches treat *O* as a predicate applied to names of act types, or as an operator on what Castañeda (1981) calls 'practitions'.) The standard definitions of 'permissible' and 'forbidden' are $Pp = \sim O \sim p$ and $Fp = O \sim p$, respectively.

Possible worlds semantics for SDL assumes that relative to any given normative system there is for each possible world *w* a non-empty set of 'deontic alternatives' for *w*. This set functions as the normative standard for *w*, so that *Op* is said to be true at *w* (relative to the given normative system) just in case *p* is true at each of *w*'s deontic alternatives.

This is put more formally in terms of model structures $\langle W, R \rangle$, where *W* is a set of possible worlds and *R* a two-place relation on *W*. An SDL model is a model structure $\langle W, R \rangle$ plus a function *I* which assigns truth-values to each $\langle p, w \rangle$, for atomic sentences *p* and worlds *w*, and obeys the usual conditions for truth-functional compounds as well as the following condition for *O*: *Op* is true at *w* in $\langle W, R, I \rangle$ just in case *p* is true in $\langle W, R, I \rangle$ at all worlds w^* such that Rww^*. A sentence *p* is valid in SDL iff it is true at all worlds of all models.

Just as there are different systems of alethic modal logic (see Modal logic), different systems of deontic logic are determined semantically by imposing various requirements on *R*. Consider, for instance, a chief respect in which the parallel between alethic and deontic notions breaks down. 'If it is necessary that *p*, then *p*' is logically valid but, to our daily chagrin, 'If *Op*, then *p*' is not. This difference is reflected in SDL by *not* requiring that *R* be 'reflexive', that is, not requiring that *w* be a deontic alternative for itself (whereas an alethic modal system would require reflexivity on its alethic-accessibility relation). For SDL we require only that *R* is 'serial'; that the set of deontic alternatives for each world is non-empty. It is this requirement that validates $Op \supset \sim O \sim p$. SDL is characterized axiomatically by tautologies *T*, *OT*, $Op \supset \sim O \sim p$ and $O(p \supset q) \supset (Op \supset Oq)$. Rules of proof are *modus ponens* and substitution. SDL can be extended by imposing additional constraints on R, such as 'reflexivity once removed' (which validates $O(Op \supset p)$) and 'transitivity' ($Op \supset OOp$), among many others.

A number of so-called 'paradoxes' in SDL motivated the development of alternative systems. The most important inadequacies of SDL were revealed by thought experiments such as Chisholm's 'contrary to duty imperative' example (1974). Normative systems often specify what should happen in case certain requirements are violated, for example, that one should apologize or pay reparations or not cry (while mopping up). A set of simple rules of this type may say, for instance, that you ought to tell neither Ann nor Bert a certain secret; and yet were you to go ahead and tell either Ann or Bert then you should tell the other as well. This set obviously is consistent. How can it be represented in SDL? If *a* abbreviates 'You tell Ann', and *b*, 'You tell Bert', $O \sim a$ and $O \sim b$ together plausibly represent the primary requirements not to tell either one the secret. What about the conditionals which tell you

what to do if you violate one of these rules? It is here that SDL gets into trouble.

A 'wide scope' representation $O(a \supset b)$ of the conditional 'You ought to tell Bert if you tell Ann' is a poor choice since it follows in SDL from $O{\sim}a$ (whereas intuitively the rules are logically independent). Moreover, there is no way to detach expression of the obligation to tell Bert, after you tell Ann: $O(a \supset b)$ and *a* together do not entail *Ob* in SDL. (The conditional $a \supset b$ may be true in all deontic alternatives and *a* true in the actual world, even though *b* is not true in all the alternatives.) A 'narrow scope' representation $a \supset Ob$ of the rule is no better since it follows from ${\sim}a$ (and yet the rule itself is logically independent of *a*). Moreover, while this option permits detachment of *Ob* given *a* by means of *modus ponens*, *Ob* is not consistent in SDL with $O{\sim}b$ (because of the validity of $Oq \supset {\sim}O{\sim}q$). So detachment generates an inconsistency that is counterintuitive, since the original rules are logically consistent with the fact that *a*. This may suggest rewriting the original unconditional obligations as ${\sim}b \supset O{\sim}a$ and ${\sim}a \supset O{\sim}b$. No inconsistent detachment is possible now, but the suggestion is not viable because the revised rule set would be wholly complied with if you told both Ann and Bert, whereas the rules obviously are violated in some sense if both *a* and *b* are true. Theorists seeking formal solutions to these problems proposed two types of response, corresponding broadly to refinements on the wide- and narrow-scope proposals.

2 Two alternatives to SDL

Von Wright proposed a new type of dyadic (two-place) deontic operator to represent expressions of conditional obligation. $O(q/p)$ is read informally as 'It ought to be that *q* given p'. Danielsson, Hansson, Lewis (1973), van Fraassen, Åqvist and others developed semantics in terms of rankings $\leq$ of worlds according to their relative acceptability (similar to the way in which orderings of worlds are used to interpret subjunctive conditionals). Let $\leq$ be a dyadic relation, on a set of worlds, which is transitive and strongly connected (that is, for any two worlds *u* and *v* in the set, either $u \leq v$ or $v \leq u$). $O(q/p)$ is true relative to $\leq$ iff some p & q-world is ranked more highly in $\leq$ than any p & ${\sim}q$-world. The unconditional *Oq* is defined as $O(q/T)$, for tautology *T*, so that *Oq* holds just in case *q* is true in all most acceptable worlds. The rules in the Ann/Bert example may be represented consistently as $\{O{\sim}a, O{\sim}b, O(a/b), O(b/a)\}$ and, significantly, it would be consistent to add further rules of the form $O({\sim}b/a \;\&\; c)$ and $O(b/a \;\&\; c \;\&\; d)$ and so on. No member of the set is entailed by any other member, and all are independent of factual circumstances. So this language is well suited for representing the content of normative systems with rules and principles that have exceptions or are 'defeasible' like $O{\sim}b$ in our example (there are circumstances, such as when *a* is true, in which $O{\sim}b$ should not be used to guide action). Since typically the rules of a system or practice are used to justify actions or states of affairs, a shortcoming of this approach taken alone is that there is no means even for expressing the unconditional 'all-out' obligations that may hold in non-ideal circumstances. For instance, in circumstances in which the non-ideal *a* is true obviously one ought (in some sense) to tell Bert because $O(b/a)$, but this obligation is not entailed by $O(b/a)$ and *a*. All most acceptable *a*-worlds may be *b*-worlds, and *a* may be true in the actual world, but nothing follows from this because the actual world may not be a most acceptable *a*-world.

A second approach, developed by Montague, Chellas (1984), Thomason (1981), van Eck (1982), Feldman (1986) and others, ties the semantics of *O* to specific factual circumstances by interpreting *O* relative to both worlds *and times*. One way to do this is to index *O* to a time *t*, so that '$O_t q$' is read 'It ought at time *t* to be that *q*' and is interpreted relative to what is 'historically necessary' (or 'settled') at *t* in *w* (see Tense and temporal logic). The set of deontic alternatives at *t* in *w* is the set of most acceptable worlds (according to a given normative system) of those that are compatible with what is settled at *t* in *w*; and $O_t q$ is true at *w* just in case *q* is true at all the deontic alternatives at *t* in *w*. So 'all-out' obligations at *t* are relative to what is settled at *t*. Let the alethic '$N_t q$' say '*q* is settled at *t*' and be true in *w* just in case *q* is true at all worlds historically possible at *t* in *w*. At times *t* when neither *a* nor *b* is settled at *w* (as in our example), $O_t{\sim}a$ and $O_t{\sim}b$ are true. But if $N_{t^*} a$, for a later time t^*, then $O_{t^*} b$.

What about the 'rules' of the system? There is no straightforward way to formalize them on this approach, though it can be done indirectly by quantifying over time: for example, $(t)({\sim}N_t a \supset O_t{\sim}b)$ replaces $O{\sim}b$, and $(t)(N_t a \supset O_t b)$ replaces $O(b/a)$. This approach works for the example and permits detachment by *modus ponens* of appropriate all-out obligation statements. The paradoxes of material implication reappear, however, so a first difficulty is distinguishing 'genuine' from spurious rules. More importantly, the formal representation of 'You should not tell Bert' as a conditional is awkward compared with the English.

3 Combining the two approaches

In any case, the elegant treatment of rules in the first approach is perfectly compatible with the second's temporal treatment of all-out obligation, and combining the two approaches also solves the main problem associated with the first. Given a ranking of worlds, all-out obligations at *t* are determined by restricting the ranking to worlds that are possible at t. If S expresses all and only what is 'settled' at *t* in *w*, then $O_t q$ is true at *w* iff $O(q/S)$ is true according to $\leq$. This means $O_t q$ is true at *w* just in case *q* is true in all most acceptable worlds, according to $\leq$, of those that are still accessible at *t* in *w*. (An agent-relative O_t can be formulated in terms of the best worlds within an agent's control.) To detach $O_t q$ from $O(q/p)$ when *p* does not express all that is settled at *t*, it is useful to express the idea that there is no *r* such that $N_t r$ and $\sim O(q/p \mathbin{\&} r)$. Let $R_t(q,p)$ say as much. This enables us to reason with $O(a/b)$ even if other rules like $\sim O(a/b \mathbin{\&} c)$ also hold. The schema $O(q/p) \mathbin{\&} N_t p \mathbin{\&} R_t(q,p) \supset O_t q$ can be validated in the combined semantics and a family of normative concepts defined precisely in its terms.

There is an 'all-out' (conclusive) reason for *q* at *t* (according to a certain normative system) iff $O_t q$ holds (for that normative system), while *q* is *prima facie* 'obligatory' at *t* iff there is some *p* such that $O(q/p)$ and $N_t p$. $O(q/p)$ is 'undercut' at *t* iff there is some *r* such that $N_t r$ and $\sim O(q/p \mathbin{\&} r)$; and $O(q/p)$ is 'overridden' at *t* iff there is some *r* such that $N_t r$ and $O(\sim q/p \mathbin{\&} r)$. $O(q/p)$ is 'defeated' at *t* iff it is either undercut or overridden. A *prima facie* reason for *q* based on $O(q/p)$ is defeated if $O(q/p)$ is defeated. There is a *prima facie* conflict at *t* iff there are p, q, r and *s* such that $N_t(q \mathbin{\&} s)$, $O(p/q)$, $O(r/s)$ and $N_t{\sim}(p \equiv r)$.

The combined system does not solve all of the problems that SDL encounters. In SDL and in the combined approach, *Op* entails *Oq* if *p* entails *q*. So, for instance, since *h*: 'You help the man who was robbed' entails *r*: 'The man was robbed', $O_t h$ entails $O_t r$, a counterintuitive result (hence the 'Good Samaritan paradox').

Also in the combined system, as in SDL, no all-out conflict (for example, of the form $O_t p \mathbin{\&} O_t q$, where *p* and *q* are contraries) is consistent, but arguably there are coherent normative systems in which genuine conflicts are a possibility, and if so it is not the business of deontic logic to legislate otherwise.

So the combined system, like SDL, is arguably too 'strong' in the sense that it validates too much. It can be weakened semantically by interpreting $O(q/p)$ not in terms of $\leq$, but rather in terms of a 'neighbourhood' selection function *f* that assigns to each proposition (set of worlds) *q* a set of subsets of *W* (the set of propositions that are obligatory given *q*). $O(q/p)$ is true iff $q \in f(p)$. Let $R_t(q,p)$ be true iff for all *r*, if $N_t r$, then $q \in f(p)$ iff $q \in f(p \mathbin{\&} r)$; and $O_t q$ is true iff there is some *p* such that $O(q/p)$, $N_t p$ and $R_t(q,p)$. $O_t p$ does not entail $O_t q$ even if *p* entails *q*, and $O_t p \mathbin{\&} O_t q$ is consistent even for contraries *p* and *q*. (In general, there is an 'all-out conflict' at *t* iff there is a *prima facie* conflict at *t*, as described above, and neither $O(p/q)$ nor $O(r/s)$ is defeated at *t*.) There is so little logical structure here (the only rule of proof is substitution) that it is difficult to envisage complaints grounded in its excessive strength. None the less, it can be used, exactly as above, to define all of the concepts defined earlier. While the weakness of this very minimal system probably is excessive, at least for applications to many normative systems, it is an appropriate starting point for developing stronger systems, and for structuring discussion of the appropriate strength of deontic logics for particular applications.

Deontological ethics

Deontology asserts that there are several distinct duties. Certain kinds of act are intrinsically right and other kinds intrinsically wrong. The rightness or wrongness of any particular act is thus not (or not wholly) determined by the goodness or badness of its consequences. Some ways of treating people, such as killing the innocent, are ruled out, even to prevent others doing worse deeds. Many deontologies leave agents considerable scope for developing their own lives in their own way; provided they breach no duty they are free to live as they see fit.

Deontology may not have the theoretical tidiness which many philosophers crave, but has some claim to represent everyday moral thought.

Deontology (the word comes from the Greek *deon* meaning 'one must') typically holds that there are several irreducibly distinct duties, such as promise-keeping and refraining from lying (see Duty; Moral pluralism). Some deontologists, such as W.D. Ross (1930), maintain that one of these duties is a duty to do as much good as possible. Most deny that there is such a duty, while conceding that there is a limited duty of benevolence, a duty to do *something* for the less fortunate (see Help and beneficence). All agree, however, that there are occasions when it would be wrong for us to act in a way that would maximize the good, because we would be in breach of some (other) duty. In this respect they are opposed to act-consequentialism (see Consequentialism §§1, 2).

Most deontologies include two important classes of duties. First, there are duties which stem from the social and personal relationships in which we stand to particular people. Parents have duties to children, and children to parents; people have duties in virtue of their jobs and the associations to which they belong; debtors have a duty to repay their creditors, promisors to keep their promises and borrowers to return what has been lent to them (see Family, ethics and the; Friendship; Professional ethics; Promising; Solidarity). Some of these social relationships are ones we enter voluntarily, but many are not. The second kind take the form of general prohibitions or constraints. We should not lie to, cheat, torture or murder *anyone*, even in the pursuit of good aims (see Truthfulness).

Deontology is often described as an agent-relative moral theory, in contrast to act-consequentialism, which is an agent-neutral theory. According to act-consequentialism the identity of the agent makes no difference to what their duty is on any particular occasion; that is determined solely by which of the courses of action open to them will produce the best consequences. In deontology, by contrast, a reference to the agent often plays an ineliminable role in the specification of the duty. This is especially clear in the case of duties which stem from social relationships. I have a duty to help *this* person. Why? Because he or she is *my* friend, or *my* child. I have a duty to pay *my* debts and to keep *my* promises.

Constraints also involve agent-relativity, though in a slightly different way. The duty not to murder does not take the form of enjoining us to minimize the number of murders. The rule tells me not to commit murder myself even if I could thereby prevent something worse being done, such as two murders being committed. Proponents of deontology think of this as moral integrity; their opponents refer to it disparagingly as 'keeping one's hands clean'.

Many deontologists hold that our duties, though sometimes very onerous, are quite limited in scope. Provided I am in breach of no duty, I am morally at liberty to devote quite a large part of my time and effort to pursuing my own projects in whatever way I please. This latitude leaves room for acts of supererogation: heroic or saintly acts that clearly go beyond the call of duty, and deserve high praise (see Supererogation).

There is a sharp division in the deontologist camp over the status of constraints. Some, such as Fried, think of them as absolute: they have no exceptions and may not be breached in any circumstances which we are likely to encounter. Others regard the fact that an act would breach a constraint as providing a weighty objection to it, but one which could be overcome if there were a sufficiently pressing duty on the other side. Conflicts between two duties which are not absolute must be settled by determining which duty is the more pressing in the circumstances.

Deontology gains much of its appeal from the fact that it seems to capture the essential outlines of our everyday moral thinking, but it is open to several objections. First, its claim that there is a plurality of distinct duties runs counter to the theoretician's search for simplicity. The deontologist will reply, of course, that a theory must do

justice to the complexity of the phenomena. Second, many deontologists further defy the supposed canons of good theorizing by denying that there is any overarching explanation of why there are the duties there are; they record our conviction that there are such duties without seeking to justify them. Others, usually inspired by Kant (1785), do attempt such an explanation based on some broader precept, such as respect for persons (see Kant, I. §§9-11; Respect for persons; Kantian ethics). Third, those who hold that some kinds of action, such as lying, are absolutely prohibited have to provide clear and detailed criteria for determining the boundary between lying and some supposedly less nefarious activity, such as 'being economical with the truth'. Such casuistry can appear both excessively legalistic and incompatible with the spirit of morality (see Casuistry). Fourth, deontology provides no procedure to settle conflicts of duty (though some might think that an advantage). Finally, from a consequentialist perspective, the notion of a constraint seems perverse. If what is wrong with murder is that it is a bad thing, how can it be rational to forbid an agent to commit one murder in order to prevent two? If deontology is to answer this challenge, it must show how it can be that one's duty does not rest (wholly) on the goodness or badness of the results of acting in that way.

Depiction

How do pictures work? How are they able to represent what they do? A picture of a goat, for example, is a flat surface covered with marks, yet it depicts a goat, chewing straw, while standing on a hillock. The puzzle of depiction is to understand how the flat marks can do this.

Language poses a similar problem. A written description of a goat will also be a collection of marks on a flat surface, which none the less represent that animal. In the case of language the solution clearly has something to do with the arbitrary way we use those marks. The word 'leg', for example, is applied to legs, but any other mark would do as well, providing we all use it in the same way. In the case of pictures, however, something different seems to be going on. There is not the same freedom in producing a picture of a goat on a hillock chewing straw - the surface must be marked in the right *way, a way we are not free to choose. So what is the right way?*

A helpful thought is that the surface must be marked so as to let us experience it in a special way. With the description, we merely need to know what the words it contains are used to stand for. With the picture, we must instead be able to see *a goat in it. However, although this does seem right, it is difficult to make clear. After all, we do not see a goat in the same way that we see a horse in a view from a window. For one thing, there is no goat there to be seen. For another, it is not even true that looking at the picture is like looking at a goat. It is partly because of the differences that, as we look at the picture, we are always aware that it is merely a collection of marks on a flat surface. So what is this special experience, seeing a goat in the picture? This is the question that a philosophical account of depiction must try to answer.*

1 The question posed

How do pictures represent? Like many other things, they represent in a variety of ways. Consider Picasso's *Guernica*. It pictures a certain scene - horses, mutilated people, a light bulb, an explosion. It expresses the horror of war, and exemplifies that art which is engaged with the moral and political world. In all these respects the picture may be said to represent something, but the forms of representation involved are not the same. Only one of these is distinctively pictorial, a form that may be dubbed 'depiction'. What is this form of representation?

One way to focus this question is to contrast depiction with other ways of representing. The most useful comparison is with words. Words and pictures may perform many of the same tasks, and may represent many of the same things; yet, at least at first glance, they seem fundamentally different. A description of the scene depicted in *Guernica* would differ considerably from the painting, and it is tempting to think that this reflects differences in the forms of representation involved. Perhaps exploring the contrast with linguistic representation will illuminate depiction itself.

2 Resemblance and its problems

Philosophers have offered many different accounts of the nature of depiction; indeed the variety can be bewildering. But there is one answer which, in the light of its venerable age and undeniable appeal, deserves early consideration. This is the thought that pictures represent by *looking like* what they depict. This appears to capture neatly the difference between the ways that words and pictures represent - *Guernica* looks like a scene of mayhem and destruction, whereas a description of such a scene does not. Moreover, the suggestion implies that depiction is a peculiarly visual form of representation - and that idea too has considerable initial appeal.

Unfortunately this view faces many difficulties, some very serious. It is natural to take the claim to be stating that one thing depicts another only if the two resemble each other in respect of some visible property. So understood, its two most important drawbacks are as follows.

First, resemblance makes demands on the world which depiction does not. For resemblance to hold, two things must exist - the thing resembling and the thing resembled. By contrast, depiction does not require there to be two things; one depicting, the other depicted. The picture alone suffices, since it may depict what does not exist. For example, it may depict a horse, but no horse in particular. (Horses exist, but none of those that do is depicted by the picture.) Alternatively, the picture may depict something of a type of which there are no instances, say a 53-sided regular polyhedron. In view of these facts, the resemblance account must do two things. It must find a

way to accommodate depiction where there is no thing depicted; and it must explain how that depiction is related to the depiction of things that do exist. This last condition is necessary, since it is now clearly possible that the account will offer two distinct analyses of depiction.

Second, the intuition that pictures look like what they depict is undermined by the difficulty of saying *in what respect* the two resemble. A picture need not resemble what it depicts in shape - *Guernica* is flat, the scene depicted is not. Nor need the two resemble in colour - a simple line drawing is black and white, but need not depict a black-and-white scene. Nor need picture and depicted match in the materials of which they are made. In fact, for any respect which might provide the resemblance, difference is as common as similarity. It seems, then, that the resemblance view may have to surrender the intuition on which it drew. Unless it can locate the putative resemblance, the thought that there must be one, and that depiction turns upon its presence, cannot be maintained.

3 Goodman’s radical alternative

The most radical reaction to these difficulties would be to abandon not merely the idea of resemblance, but also the strong contrast between depiction and linguistic representation, and the idea that the former is peculiarly visual. The key exponent of such an approach, and indeed of the criticisms of resemblance that motivate it, is Nelson Goodman (§2).

Goodman locates the difference between the ways in which pictures and words represent things in formal features of the representational systems in question. To do this, he develops a set of theoretical tools. Marks on surfaces are grouped as inscriptions of different characters. For example, you are currently looking at marks, each of which is an inscription of a character in the Roman alphabet. Characters are grouped so as to form symbol schemes - the Roman alphabet is one such scheme, while the first eight characters in it form another. If the characters are correlated with a field of reference, the result is a symbol system. Examples include the system for naming the eight notes in a musical octave, and, at a higher level of complexity, written English.

What is special about symbol systems that are pictorial?Goodman identifies three important features. First, such systems are ‘syntactically dense’. That is, they involve infinitely many characters, and are ordered so that between any two characters lies a third. Second, they are ‘semantically dense’. The field of reference of the characters is so ordered that between any two referents there is a third. Finally, they are ‘relatively replete’ - a relatively wide range of properties of the mark determines which character it inscribes. Roughly, this amounts to the following. Pictorial systems are ones in which, for a wide range of properties of the mark on the surface, the tiniest differences in that property affect what is represented. This is not so for linguistic systems - consider, for instance, the English names for the constellations. More generally, Goodman claims that all three features are exhibited by pictorial systems, and that they are not all exhibited by those which represent linguistically. Beyond this simple differentiation claim he is reluctant to tread.

Many of Goodman’s critics have sought to attack his position by counterexample. A graph might be used to track the various properties of a colourless gas over time. With ‘time elapsed’ represented by distance along the x-axis and temperature along the y-axis, thickness of the plotted line might represent the density of the gas, colour might represent its radioactivity, and so on. Such a graph could be a symbol in a system that is both syntactically and semantically dense, and relatively replete. No difference in the graph is in principle too small to affect the precise state of the gas represented. Despite this, the graph would not depict anything.

It has not always been recognized that these examples prove little as they stand, save that Goodman was right not to claim to provide conditions sufficient for depiction. None the less, they may be used to make a stronger case against Goodman since they raise the question *why* it is so plausible that, in this example, the graph does not depict the gas.

One plausible answer is that this representation lacks certain features common to all depiction. For one thing, the graph does not represent the gas from any particular point of view. Pictures, by contrast, always represent what they depict from some perspective - sometimes several. Further, the graph does not represent any properties of the gas that are properties of its visual appearance. The gas has no visual appearance, and is not represented as having one. But, again, depiction is always the representation of things as having an appearance. Finally, although the graph has a comparatively complex content, it might easily not have done so. Had every one of the above features fed in some weighted manner into the representation of the temperature of the gas, the graph would still have met

Goodman's conditions for belonging to a pictorial symbol system, but would have represented nothing more than temperature. Yet pictures always have comparatively detailed contents, even when relatively schematic. This, after all, is the truth of the common saying 'a picture paints a thousand words'.

The force of the example can now be made clear. It not only shows that the account is incomplete, but also indicates how seriously it is so. The graph, at least in its second form, meets Goodman's differentiation conditions without having any of the three features characteristic of depiction. An adequate theory of depiction must be a theory of a form of representation with those features, and should ideally explain why they hold. As it stands Goodman's account plainly does not meet either of these requirements. Moreover, it does not seem that it could readily be developed to meet them. For what might be added to the specification of formal features of the symbol system so as to obtain this result? It seems that the only emendations to suffice would amount to gerrymandering. Thus the only course, if these features are to be accommodated, seems to be to return from Goodman's radicalism towards views which bind depiction more closely to the visual.

4 Our experience of pictures

One such course which has very often been proposed in some form or other is an appeal to the idea that depictions are *experienced* in a special way. Suppose yourself confronted by a picture, but one you do not yet understand at all. You can see quite clearly what colour lies where on its surface. Perhaps you can even see *that* it is a picture of something or other; certainly your experience may give you good grounds to suspect this. But you cannot see what is depicted by the picture. Then, in a moment, you 'get the point'. You can see that the picture is of a horse, that the strange shaped lump that had puzzled you depicts its head, those straggly lines of colour depict its legs, and so forth. It does not seem to you that anything in your environment has altered. You still see the same patches of colour in the same locations. And yet in some sense things now look very different. You see the surface organized in a way you could not see before.

There are two experiences of the picture here, one accompanying the successful interpretation, the other preceding it. The second experience has a distinctive phenomenology, or subjective character, for anyone who enjoys it. It is a way of seeing the coloured surface, but a way somehow involving the thought of what is absent - in this case, a horse. And it is, in some sense, an integrated whole; unlike, for instance, the experience of seeing a castle while visualizing a horse.

Some, most notably Richard Wollheim (1987), have argued that every picture can in principle be experienced in two ways, parallel to those above. Moreover, they have claimed that experiences like the second hold the key to depiction. The idea is that in those experiences one's awareness of the picture's surface involves the thought of something else, and that thing is just what the picture depicts. In the standard terminology, one *sees* in the picture what is depicted. For such philosophers, the key task is to characterize this experience more fully. After all, what has been said thus far fails to distinguish 'seeing-in' from many other experiences, those forming one sort of aspect perception (see Wittgenstein, L.).

Wollheim's own account of the experience of seeing one thing in another is as follows. It is a visual experience of a differentiated surface, and has two 'folds', or aspects. One aspect is in some way analogous to the experience of seeing the surface without seeing anything in it. The other is in some way analogous to the experience of seeing (face-to-face) whatever is seen in the surface. It is not possible to say anything illuminating about the nature of the analogies here involved; indeed to ask for such clarification would be a sign of confusion.

Of those sympathetic to this broad approach, many have thought that more than this can be said. This response is vindicated by the need to offer an account of depiction that accommodates the features mentioned in §3. For unless Wollheim can say more about seeing-in, he cannot hope to offer explanations of those features. Consider, for example, the fact that depiction is always from a point of view. It is natural for the defender of seeing-in to try to account for this by tying what is depicted to what is seen in a surface, and then by establishing that seeing something in a surface itself necessarily involves a point of view on that absent item. But what reason can there be to assert this last claim? The answer must come from the fact that one fold of seeing-in is analogous to an experience, that of seeing the absent item face-to-face, which itself necessarily involves a point of view. However, this is only the sketch for an explanation until that analogy is clarified - what features of the analogy guarantee the presence of perspective in the fold, given its presence in the analogous experience?

There have been other attempts to characterize seeing-in, but the obstacles to success are considerable.Kendall Walton, for instance, makes skilful use of an appealing idea: that seeing-in involves the visual imagination (1990). In essence, his claim is that when I see a horse in a picture, I imagine of my seeing the picture's surface, that it is my seeing a horse. The fundamental difficulty with any such view is that it is ambiguous, and that on either reading it is equally problematic. The ambiguity turns on whether or not the imagining in question involves visualizing. Visualizing has its own distinctive phenomenology. For this reason, it is plausible to claim that any experience with which it is involved will have a distinctive character informed by that phenomenology, but hard to see how that experience can form an integrated whole. On the other hand, imagining that is not visualizing lacks any distinctive phenomenology. It is therefore easy to integrate into a unified experience, but ill-suited to contributing to a distinctive character. Since seeing-in is both phenomenologically distinctive and an integrated whole, the prospects for characterizing it using the imagination are not good (see Imagination).

5 Interpreting depiction

The task of characterizing seeing-in is one of the most challenging in this area. Given this, and scepticism about some of the central notions which any such characterization must deploy, there have been attempts to clarify in other ways the thought that depiction is peculiarly visual. For example, some have attempted to analyse depiction using the epistemic resources required to interpret it. The idea is that what is special about pictures, as opposed to words, is what one needs to know in order to interpret them. For language, one must know the conventions governing the words' use, conventions specific to individual words. Understanding pictures, in contrast, requires a rather different sort of knowledge. Flint Schier, for example, claims that one must know what the depicted item looks like (1986). Moreover, this is in essence *all* one needs to know to interpret pictures, provided that one has a general competence with depiction, that is, the ability to interpret any pictures at all. Since this is so, Schier speculates that a depiction of something engages our ability to recognize that thing, and that it is definitive of depiction to do so.

Schier's view has many advantages. In particular, it finally allows for accommodating and explaining the features of depiction noted in §3. Pictures engage our abilities to recognize what they depict, but those abilities are relative to points of view. I may be able to recognize you seen from the front, while being unable to do so from directly above you. So what individual pictures must engage is the ability to recognize what they depict from a particular point of view - hence the perspectival nature of depiction. Further, visual recognitional abilities are engaged in clusters, rather than singly - I recognize you because I recognize a person with such and such features standing before me. So if a picture is to engage a visual recognitional ability of mine, it will engage others at the same time. Thus there is no depicting something without depicting it as having a certain appearance, and there is no depiction which is not fairly complex in content.

Despite this, there is one form of attack to which Schier's position is vulnerable. For, as he himself admits, it is tempting to think that there is a deeper explanation for why depiction engages our recognitional capacities - that pictures do after all resemble what they depict. If this line can be made good, explanations can not only be provided for the features of §3, but forSchier's view too, along with his observations on the epistemic resources depiction requires. However, the problems facing the resemblance view were severe. Can solutions be found for them?

6 Resemblance revisited

The intuition that pictures look like what they depict was clarified above in the claim that depicting and depicted resemble in respect of some visible property. The discussion of seeing-in provides an opportunity to present the intuition another way. Depiction should be understood by characterizing our experience of it. Thus the better way to understand the intuition is as advocating a certain view of seeing-in: that it is the experience of likeness.

So understood, the view fares somewhat better with the first problem presented in §2. Resemblance may require there to be two things, one resembling, one resembled; the experience of resemblance does not. For instance, I may experience a sound I hear as resembling another, even if that other sound is one I have merely on occasion conjured in my imagination, and even if I am fully aware of this. This opens the way for a single account of depiction, whether or not there exists something depicted. In either case, the picture is experienced in a special way. It is seen in a way somehow involving the thought of the thing depicted (existing or not), and the proposal is

to understand that way of seeing the picture as an experience of resemblance.

However, this still leaves the second problem entirely untouched. In what respect is resemblance experienced? For it is no more plausible to say that a picture need be *experienced as* resembling what it depicts in shape, colour, material composition and the like than it is to say that the two must resemble in those respects.

The answer lies in a property of things that we regularly perceive, but rarely articulate. Consider the thought that in one way a circular disk seen at an oblique angle looks elliptical, yet for all that its 3-D shape is clearly unchanged. What is picked out here is a shape property of an unusual kind. For it is relative to a point - in this case, the point from which the disk is seen. In fact, it is the property of subtending a certain solid angle at that point. For convenience, call this property the ‘outline shape’ the disk has at that point. This is not, however, simply the shape of the object’s silhouette. For if the disk is marked with concentric circles, each of those will also subtend a certain solid angle at the point, and the outline shape of the whole may be taken to include these nested sets of angles too. So understood, it is at least clear that many pictures which do not resemble what they depict in 3-D shape may do so in outline shape.

Seeing-in, then, is essentially the experience of likeness in respect of outline shape. Depiction may then be understood as that representation which works through the deliberate generation of this experience. This leaves many details to work through, and many objections to counter. None the less it is a position with great promise. For it offers a way to perform all the most pressing tasks encountered above - accommodating our intuitions about depiction, explaining various of its features, and characterizing the experience to which it gives rise.

Derrida, Jacques (1930-)

Jacques Derrida is a prolific French philosopher born in Algeria. His work can be understood in terms of his argument that it is necessary to interrogate the Western philosophical tradition from the standpoint of 'deconstruction'. As an attempt to approach that which remains unthought in this tradition, deconstruction is concerned with the category of the 'wholly other'.

Derrida has called into question the 'metaphysics of presence', a valuing of truth as self-identical immediacy which has been sustained by traditional attempts to demonstrate the ontological priority and superiority of speech over writing. Arguing that the distinction between speech and writing can be sustained only by way of a violent exclusion of otherness, Derrida has attempted to develop a radically different conception of language, one that would begin from the irreducibility of difference to identity and that would issue in a correspondingly different conception of ethical and political responsibility.

1 Historical context and influences

To identify all of the philosophical problematics at stake in Derrida's writings, it would probably be necessary to have some familiarity with the works of Kant, Hegel, Marx, Nietzsche, Husserl, Heidegger, Levinas, Saussure, Lévi-Strauss, Austin, Foucault, Freud, Lacan, Nicolas Abraham and Maria Torok. Lacking such familiarity, readers of Derrida are often not in a position to recognize - let alone assess - the philosophical moves he makes. Ill-equipped commentators have ascribed to Derrida theses that have nothing to do with his actual philosophical concerns. Some of the confusion can be traced to the borrowing of Derrida's term 'deconstruction' by the literary critic Paul De Man and others for whom the term has come to refer to a style of reading texts. For Derrida, deconstruction is less a reading technique than it is a way of approaching the 'wholly other' and of attempting thereby to conjure 'an experience of the impossible'.

Derrida's work can be situated within the broad constellation of post-Hegelian efforts to consider whether a rigorous critique of the language of metaphysics can free philosophical thinking from its regularly repeated dogmatic gestures. The theme of avoiding metaphysical dogmatism is one that could be traced back to Kant and the British empiricists, and even to Descartes in certain respects. But criticizing metaphysical *dogmatism* and criticizing metaphysical *language* are not necessarily the same enterprise, and it is only in the post-Hegelian world that the project of interrogating language becomes a steady theme for Western philosophers. Defined in this way, the constellation of figures to which Derrida belongs would include members of the pragmatist and logical positivist movements as much as it would those thinkers associated with continental philosophy. But it is primarily out of the continental tradition that Derrida's own philosophical concerns have developed.

In his earliest writings, Derrida is drawn to the Husserlian phenomenological project as a rigorous attempt to develop an account of signification (see Husserl, E.). Noting, however, that Husserl retains the philosophical ideal of univocal language, Derrida argues that Husserl's phenomenological method remains motivated by a traditional metaphysical appeal to the value of truth as self-presence. To some extent, Heidegger had already criticized Husserlian phenomenology on similar grounds. Appreciative of Heidegger's arguments but also hesitant about some of his conclusions, Derrida takes Heidegger's attempt to define a 'task for thinking' at the 'end of philosophy' to pose a number of crucial questions to which he has repeatedly returned in his own work.

In his later writings, Heidegger critiques the claim that language is something which 'belongs to man', substituting for this the attempt to show how 'man belongs to language'. Were he simply advancing a proposition thereby, Heidegger would seem to be saying that thought does not determine language; rather, language determines thought. But it would be a mistake to read Heidegger as making an empirical claim of the Whorfian variety. If the beings that comprise the world manifest themselves as such only by way of language, then language is that which opens up the world *as such* - that is, as a sphere of particular beings which can be studied empirically. Such a claim would be analogous to the Kantian thesis that the basic categories of human thought are not mere empirical concepts which we get from our observation of objects; rather, they constitute the very objectivity of the world. Kant's thesis is transcendental. For Heidegger, the fact that different languages constitute the world differently for different speakers renders problematic the Kantian appeal to universal concepts. If thinking is always limited by a finite language which it cannot master, it follows that thinking can at most raise regional problems about the ways

in which it is so determined.

2 Deconstruction

It is out of his reflections on the implications of this position that Derrida comes to clarify the task of deconstruction. Derrida first proposed the French *déconstruction* as a way of translating Heidegger's use of the German word *Destruktion*, a term which appears in *Being and Time* (1927). According to Heidegger, the task of thinking time as the horizon of Being requires a *Destruktion* of the history of metaphysical concepts, especially the concept of time as developed in Aristotle, Descartes, and Kant. Heidegger does not equate *Destruktion* with obliteration. For Heidegger, the history of metaphysics consists in the tightening of a structure - what he later calls the *Gestell* - and it is his aim to 'loosen' the hold that this structure has on thinking. Considered in this way, *Destruktion* would be a freeing-up: a de-structuring. It is partly in order to capture this particular sense of the Heideggerian term that Derrida invokes the word *déconstruction*.

But Derrida takes his work of translation to be one which also transforms the Heideggerian conception of 'freeing-up', for Derrida sees Heidegger as recapitulating certain gestures of the metaphysics of presence. Derrida is especially suspicious of those places where Heidegger seems to suggest that the *Destruktion* of the history of metaphysics can bring thought back to some sort of 'original' relation to language as a poetic 'Saying' of 'the Being of beings'. For Derrida, there can be no 'original' position from which thinking begins or to which it could return.

For Derrida, the history of Western metaphysics consists in a series of repeated efforts to affirm self-presence as the paradigm of truth. At the heart of this tradition is the definition of 'man' as that being who can signal his self-presence to himself through language. Against this pretension of 'man's' unique position among beings - and in crucial respects his position here is closer to Hegel's than is usually acknowledged - Derrida argues that no thought, not even that of an 'I think', can ever be immediately present to itself (see Selfhood, postmodern critique of). To understand this position, we need to see why Derrida is drawn away from the theme of language to that of writing.

In order to maintain the value of self-presence, Western philosophers have traditionally tended to ignore the degree to which thinking is dependent on language. Yet the fact of such dependence could not be dismissed entirely. Accordingly, philosophers from Plato to Rousseau to Hegel distinguish between an ideal language in which thought would be immediately transparent to itself, and a secondary language into which this original and univocal 'language of thought' could then be translated. *Spoken* words - because they exist only in the disappearing moment in which they are spoken, and because they can be heard 'in the head' of the speaker - would seem to be directly expressive of thought. By contrast, *written* words, because they can function even in the absence of their producer, would seem to be exterior to thought. Speech immediately embodies thought; writing is merely a sign of speech: such would be the founding claim of philosophy's pretension to self-presence through a forgetting of the materiality of signification. On the basis of this flimsy argument, Western philosophers writing alphabetically have insisted that their own 'phonetic' writing is more intelligible - that is, a sign of greater intelligence - than the 'non-phonetic' writing of non-Europeans - this despite the contravening fact that, as in Leibniz, the ideal of a formal language has necessarily found its exemplar in the model of non-phonetic writing.

Obviously, there are all kinds of empirical reasons why it should seem impossible to say what counts as phonetic writing and what counts as non-phonetic writing. More significantly, Derrida argues, it is impossible to make sense of the ideal of a purely expressive language. For in its dependence on iterable signifiers, all language requires that very non-expressive element which has traditionally been ascribed to non-phonetic writing. Accordingly, there is simply no basis for drawing a rigorous distinction between 'speech' and 'writing'.

In this way, Derrida purports to deconstruct the 'logocentric' or 'phonocentric' basis of the metaphysics of presence. The hierarchical privileging of speech over writing turns out to be but one of an indefinite series of hierarchical oppositions upon which traditional metaphysics founds itself. In each case, that which would function as something 'other' to the pretension to self-presence is excluded by being accorded the same 'fallen' status that non-phonetic writing is said to have. Derrida's aim is not to 'reverse' these hierarchical oppositions - as it would be if he were interested in privileging writing over speech - but to deconstruct the very logic of such exclusionary founding gestures.

On Derrida's account, then, the untenability of the speech/writing distinction makes the concept of writing just as suspect as the concept of speech. On the other hand, writing continues to function as an exemplary figure of otherness. For this reason, it is tempting to say that, much as Heidegger suggests that the task of thinking is 'to bring language as language to language', so deconstruction tries 'to bring writing as writing to writing'. To deconstruct the metaphysics of presence would be to disclose thinking *as* writing - rather than writing as a way of recording pure thoughts. Derrida stresses this point by describing 'arche-writing' - the archival character of a thought without *arkhe*, or origin - as *différance*, a term he introduces to name the impossibility of naming a 'first' or 'central' term of any sort. As a way of opening up the possibility for thinking otherwise than metaphysically, it is necessary to free up writing from its metaphysical interpretation as language intended to express a self-present 'meaning' or 'truth'.

Toward this end, Derrida has developed a number of different writing strategies. One strategy is to produce irreducibly multiple 'texts' which resist being read as unified 'books'. Derrida's *Glas* (1974; the word can be translated as 'death knell') is fragmented in this way. Its basic structure consists of two separate 'columns', one of which examines a number of issues related to Hegel's conception of a crypt, and the other of which juxtaposes to this first column a multi-faceted examination of the signature of Jean Genet as a kind of crypt that is regularly inscribed in Genet's writings. Among other things, *Glas* can be read as a deconstruction that would 'free up' the writings of Genet from the quasi-Hegelian 'summing-up' of Genet which Sartre presented in his *Saint Genet* (1952). Another strategy of Derrida's is to produce textual marks - such as *différance* - that are specifically designed to render problematic the traditional concept of a signifier. Such marks are not quite 'neologisms', since they are neither words nor signifiers, but deconstructive 'surds' which call attention to their own resistance to intelligibility.

3 Early reception and subsequent clarifications

The thematics of *différance* have given rise to a number of misunderstandings about Derrida's work, and some of his writings of the 1980s and 1990s are attempts to specify the task of deconstruction more precisely. The fact that *différance* indicates the un-sayability of a 'final word' about something like 'Being' has been read by some as resonating with the language of negative theology. Derrida shows why the apparent affinity is unavoidable but warns that to equate deconstruction with negative theology would be to reaffirm the eschatological orientation of the metaphysics of presence. Instead, Derrida has argued that every experience is structured by an undeconstructible messianic promise which interrupts the presence of the here-and-now without being reducible to the prophecy of a determinate future. Perhaps the Heraclitean conception of 'becoming' comes closest to indicating what Derrida is after with his writing of *différance* - provided that we read Heraclitus' affirmation of becoming as compatible with Derrida's account of the experience of the promise.

Such a reading of Heraclitus can perhaps be found in Nietzsche's writings, the deconstructive aspects of which Derrida takes Heidegger to overlook. According to Heidegger, Nietzsche's texts represent the single thought of a single thinker at a singular moment in the history of Being. Derrida counters this suggestion by calling attention to aspects of Nietzsche's writing styles. Rather than express a meaning or truth, Nietzsche's writings introduce textual problematics meant to rule out recourse to the traditional conceptual resources of interpretation. Derrida demonstrates this, in *Éperons: les styles de Nietzsche (Spurs: Nietzsche's Styles)*, by showing the difficulties that would arise for any interpretive decision concerning a scrap of paper on which Nietzsche has scribbled (in German) 'I have forgotten my umbrella.' At issue is not only the question of whether a text can have a single meaning, but whether it makes sense to speak of any 'thing' as having a single identity. Rather than speak of *Nietzsche*'s texts, Derrida writes of those texts that are signed with the *signature* - or, as it will turn out, signatures - of 'Nietzsche'. The problematic of the signature thereby becomes an important issue which arises in many of Derrida's texts, and the question of his 'own' signature features prominently in these considerations. Derrida is especially attentive to what he calls the 'iterability' of signatures - their ability, as marks, to function in the absence of any determinable addressee. On Derrida's analysis, iterability (which is the condition for the possibility of a written mark's ability to function as a signifier) disrupts the concept of a fixed context that would determine a set of rules governing signification.

Although he has seemed, to some critics, merely to duplicate the writing strategies of Nietzsche, Derrida expresses some reservations about certain of Nietzsche's gestures. For example, while he notes that the term 'woman'

functions in Nietzsche's writings as a trope for non-truth - and thus as an exemplary textual 'site' for deconstruction - he also calls attention to the violence of such gestures. Derrida seeks a strategy that would exploit the subversive potential of marginal subject positions without reifying the logic of marginality. In this way, deconstruction becomes a way of thinking about the political. From his earliest writings Derrida has been concerned with the relationship between justice and violence. Taking off from Heidegger's essay on the Anaximander Fragment (1946), Derrida engages Levinas and others on the question of whether or not it is possible to thematize a purely non-violent conception of justice.

What exactly a more fully developed deconstructive politics might look like is a topic that has received a great deal of attention in recent years. The fact that *différance* implies an endless deferral of what, from the standpoint of metaphysics, would be the 'meaning' or 'truth' of beings (or of Being), has led some critics to suggest that deconstruction undermines the very possibility of making ethical and political determinations. Such interpretations overlook the constant concern with justice that informs Derrida's works. Working both with and against the Kantian conception of regulative ideals, Derrida seeks to delineate a conception of justice as an *aporia* which both calls for, and is called forth by, the work of deconstruction.

Despite evidence to the contrary, Habermas, Gadamer and their followers insist that deconstruction implies an affirmation of indeterminacy and thus the complete inability to make political judgments. These critics argue for a politics based on an ideal of consensus, and they take to task philosophers such as Derrida who do not share their consensus that consensus is a goal that no one needs to be coerced to accept. By calling nearly every position substantively different from his own a 'performative contradiction', Habermas exhibits the very sort of normative violence that deconstruction questions.

Derrida has countered such criticisms by more explicitly addressing ethical and political issues. Toward this end, he has drawn on a wide variety of traditional texts, among them Aristotle and de Montesquieu on friendship; Aristotle on the difference between economics and chrematistics; Marx on commodity fetishism; Kant on international politics, and Benjamin on the messianic. A constant concern of Derrida's has been that of developing a rigorously deconstructive conception of responsibility, a theme he often develops with reference to the work of Levinas.

Derrida's contributions to social theory cannot be fully understood, I would argue, without some sense of his response to Nicolas Abraham and Maria Torok's recasting of psychoanalytic problematics along lines that connect Husserlian and Freudian conceptions of subjectivity. Abraham and Torok's reworking of such psychoanalytic concepts as incorporation, introjection, mourning and haunting, are frequently invoked in Derrida's writings. In *Spectres de Marx (Specters of Marx)*, Derrida develops a conception of 'hauntology' which uses many of these terms to work through questions concerning the texts of Marx and the political programmes associated with Marxism. Making explicit a complex problematic of 'the spectral' in Marx's texts, Derrida juxtaposes the force of Marx's account of the spectrality involved in commodity fetishism with Marx's resistance to the concept of spectrality. By way of considering Marx's conflicted relationship with Stirner, Derrida calls for a return to a Marxist thinking that would not banish the spectral dimension which Stirner opens up. In so doing, Derrida implicitly suggests that Marx's attempt to banish Stirnerian concerns parallels the attempt of contemporary social theorists to 'conjure away' the spectre of deconstruction.

List of works

Derrida, J. (1962) 'Introduction', in E. Husserl, *L'Origine de la géometrie*, trans. J. Derrida; trans. D. Allison, *Edmund Husserl's 'Origin of Geometry': An Introduction*, Pittsburgh, PA: Duquesne University Press, 1978. (Critique of the value of univocity in Husserl's account of ideality.)

Derrida, J. (1967a) *La Voix et le phénomène*, trans. D. Allison, *Speech and Phenomena and Other Essays on Husserl's Theory of Signs*, Evanston, IL: Northwestern University Press, 1973. (Argues that the indicative, or written, element of language cannot be reduced in Husserl's account of meaning.)

Derrida, J. (1967b) *De la grammatologie*, trans. G. Spivak, *Of Grammatology*, Chicago, IL: University of Chicago Press, 1974. (Shows that the history of philosophy has been governed by a privileging of speech over writing.)

Derrida, J. (1967c) *L'Écriture et la différence*, trans. A. Bass, *Writing and Difference*, Chicago, IL: University of Chicago Press, 1978. (Includes the important essay, 'De l'économie restreinte à l'économie générale: un hégélianisme sans réserve' (From Restricted to General Economy: A Hegelianism Without Reserve) as well as essays on Foucault and Levinas.)

Derrida, J. (1972) *Marges - de la Philosophie*, Paris: Éditions de Minuit; trans. A. Bass, *Margins of Philosophy*, Chicago, IL: University of Chicago Press, 1982. (Includes 'Le Puits et la pyramide: introduction à la sémiologie de Hegel' (The Pit and the Pyramid: Introduction to Hegel's Semiology) in which he discusses Hegel's theory of signs, and essays on Heidegger and other philosophers.)

Derrida, J. (1974) *Glas*, Paris: Éditions Galilée; trans. J. Leavey and R. Rand, Glas, Lincoln, NE: University of Nebraska Press, 1986.(Difficult but richly textured readings of Hegel and Genet.)

Derrida, J. (1978) *Éperons: les styles de Nietzsche*; trans. B. Harlow, *Spurs: Nietzsche's Styles*, Chicago, IL: University of Chicago Press, 1979. (A short, and in some ways exemplary, deconstructive reading of Nietzsche.)

Derrida, J. (1987) *De l'esprit: Heidegger et la question*; trans. G. Bennington and R. Bowlby, *Of Spirit: Heidegger and the Question*, Chicago, IL: University of Chicago Press, 1989. (Examines the use of the German term *Geist* and its derivatives in Heidegger.)

Derrida, J. (1992) 'Force of Law: The "Mystical Foundation of Authority"', in D. Cornell, M. Rosenfeld and D.G. Carlson (eds) *Deconstruction and the Possibility of Justice*, New York: Routledge. (Widely cited essay in which Derrida distinguishes between justice and law.)

Derrida, J. (1993) *Spectres de Marx*; trans. P. Kamuf, *Specters of Marx*, Chicago, IL: University of Chicago Press, 1994. (Juxtaposes readings of *Hamlet*, Heidegger and Marx as a way of conceiving the relationship between justice, mourning, responsibility and spectrality.)

References and further reading

Abraham, N. and Torok, M. (1994) *The Shell and the Kernel*, vol. 1, trans. and ed. N. Rand, Chicago, IL: University of Chicago Press. (An important collection of essays that have influenced Derrida's attempt to think together certain phenomenological and psychoanalytic themes.)

Descartes, René (1596-1650)

René Descartes, often called the father of modern philosophy, attempted to break with the philosophical traditions of his day and start philosophy anew. Rejecting the Aristotelian philosophy of the schools, the authority of tradition and the authority of the senses, he built a philosophical system that included a method of inquiry, a metaphysics, a mechanistic physics and biology, and an account of human psychology intended to ground an ethics. Descartes was also important as one of the founders of the new analytic geometry, which combines geometry and algebra, and whose certainty provided a kind of model for the rest of his philosophy.

After an education in the scholastic and humanistic traditions, Descartes' earliest work was mostly in mathematics and mathematical physics, in which his most important achievements were his analytical geometry and his discovery of the law of refraction in optics. In this early period he also wrote his unfinished treatise on method, the Rules for the Direction of the Mind, which set out a procedure for investigating nature, based on the reduction of complex problems to simpler ones solvable by direct intuition. From these intuitively established foundations, Descartes tried to show how one could then attain the solution of the problems originally posed.

Descartes abandoned these methodological studies by 1628 or 1629, turning first to metaphysics, and soon afterwards to an orderly exposition of his physics and biology in The World. But this work was overtly Copernican in its cosmology, and when Galileo was condemned in 1633, Descartes withdrew The World from publication; it appeared only after his death.

Descartes' mature philosophy began to appear in 1637 with the publication of a single volume containing the Geometry, Dioptrics and Meteors, three essays in which he presented some of his most notable scientific results, preceded by the Discourse on the Method, a semi-autobiographical introduction that outlined his approach to philosophy and the full system into which the specific results fit. In the years following, he published a series of writings in which he set out his system in a more orderly way, beginning with its metaphysical foundations in the Meditations (1641), adding his physics in the Principles of Philosophy (1644), and offering a sketch of the psychology and moral philosophy in the Passions of the Soul (1649).

In our youth, Descartes held, we acquire many prejudices which interfere with the proper use of our reason. Consequently, later we must reject everything we believe and start anew. Hence the Meditations begins with a series of arguments intended to cast doubt upon everything formerly believed, and culminating in the hypothesis of an all-deceiving evil genius, a device to keep former beliefs from returning. The rebuilding of the world begins with the discovery of the self through the 'Cogito Argument' ('I am thinking, therefore I exist') - a self known only as a thinking thing, and known independently of the senses. Within this thinking self, Descartes discovers an idea of God, an idea of something so perfect that it could not have been caused in us by anything with less perfection than God Himself. From this he concluded that God must exist which, in turn, guarantees that reason can be trusted. Since we are made in such a way that we cannot help holding certain beliefs (the so-called 'clear and distinct' perceptions), God would be a deceiver, and thus imperfect, if such beliefs were wrong; any mistakes must be due to our own misuse of reason. This is Descartes' famous epistemological principle of clear and distinct perception. This central argument in Descartes' philosophy, however, is threatened with circularity - the Cartesian Circle - since the arguments that establish the trustworthiness of reason (the Cogito Argument and the argument for the existence of God) themselves seem to depend on the trustworthiness of reason.

Also central to Descartes' metaphysics was the distinction between mind and body. Since the clear and distinct ideas of mind and body are entirely separate, God can create them apart from one another. Therefore, they are distinct substances. The mind is a substance whose essence is thought alone, and hence exists entirely outside geometric categories, including place. Body is a substance whose essence is extension alone, a geometric object without even sensory qualities like colour or taste, which exist only in the perceiving mind. We know that such bodies exist as the causes of sensation: God has given us a great propensity to believe that our sensations come to us from external bodies, and no means to correct that propensity; hence, he would be a deceiver if we were mistaken. But Descartes also held that the mind and body are closely united with one another; sensation and other feelings, such as hunger and pain, arise from this union. Sensations cannot inform us about the real nature of things, but they can be reliable as sources of knowledge useful to maintaining the mind and body unity. While many of Descartes' contemporaries found it difficult to understand how mind and body can relate to one another,

Descartes took it as a simple fact of experience that they do. His account of the passions is an account of how this connection leads us to feelings like wonder, love, hatred, desire, joy and sadness, from which all other passions derive. Understanding these passions helps us to control them, which was a central aim of morality for Descartes.

Descartes' account of body as extended substance led to a physics as well. Because to be extended is to be a body, there can be no empty space. Furthermore, since all body is of the same nature, all differences between bodies are to be explained in terms of the size, shape and motion of their component parts, and in terms of the laws of motion that they obey. Descartes attempted to derive these laws from the way in which God, in his constancy, conserves the world at every moment. In these mechanistic terms, Descartes attempted to explain a wide variety of features of the world, from the formation of planetary systems out of an initial chaos, to magnetism, to the vital functions of animals, which he considered to be mere machines.

Descartes never finished working out his ambitious programme in full detail. Though he published the metaphysics and the general portion of his physics, the physical explanation of specific phenomena, especially biological, remained unfinished, as did his moral theory. Despite this, however, Descartes' programme had an enormous influence on the philosophy that followed, both within the substantial group that identified themselves as his followers, and outside.

1 Life

René Descartes was born on 31 March 1596 in the Touraine region of France, in the town of La Haye, later renamed Descartes in his honour. In 1606 or 1607 he was sent to the Collège Royal de La Flèche, run by the Jesuit order. Here he received an education that combined elements of earlier Aristotelian scholasticism with the new humanistic emphasis on the study of language and literature. But the core of the collegiate curriculum was the study of Aristotelian logic, metaphysics, physics and ethics. Descartes left La Flèche in 1614 or 1615, and went to the University of Poitiers, where he received his *baccalauréat* and his *licence en droit* in late 1616. In Part I of the *Discours de la méthode (Discourse on the Method)* (1637), he discusses his education in some detail, explaining why he found it increasingly unsatisfactory. In the end, he reports, he left school, rejecting much of what he had been taught there. He chose the life of the military engineer, and set out across Europe to learn his trade, following the armies and the wars. On 10 November 1618, in the course of his travels, he met Isaac Beeckman. An enthusiastic scientific amateur since his early twenties, Beeckman introduced Descartes to some of the new currents in science, the newly revived atomist ideas, and the attempt to combine mathematics and physics (see Atomism, ancient). Despite the fact that they only spent a few months together, Beeckman put Descartes on the path that led to his life's work. A number of discussions between them are preserved in Beeckman's extensive notebooks (1604-34), which still survive, and include problems Beeckman set for Descartes, as well as Descartes' solutions. It was for Beeckman that Descartes wrote his first surviving work, the *Compendium musicum*, a tract on music theory, then considered a branch of what was called mixed mathematics, along with other disciplines such as mathematical astronomy and geometric optics. Exactly a year after first meeting Beeckman, this new path was confirmed for Descartes in a series of three dreams that he interpreted as a call to settle down to his work as a mathematician and philosopher.

During the 1620s, Descartes worked on a number of projects including optics and the mathematics that was eventually to become his analytic geometry. In optics, he discovered the law of refraction - the mathematical law that relates the angle of incidence of a ray of light on a refractive medium, with the angle of refraction. Though some claim that Descartes learned this law from Willebrod Snel, after whom the law is now named, it is generally thought that Descartes discovered it independently. In his mathematical programme, he showed how algebra could be used to solve geometric problems, and how geometric constructions could be used to solve algebraic problems.

Descartes' most extensive writing from this period is the *Regulae ad directionem ingenii (Rules for the Direction of the Mind)*, a treatise on method that he worked on between 1619 or 1620 and 1628, when he abandoned it incomplete. He continued to travel extensively throughout Europe, returning to Paris in 1625, where he was to stay until spring 1629. In Paris, Descartes became closely associated with Marin Mersenne who later became a central figure in the dissemination of the new philosophy and science in Europe, the organizer of a kind of scientific academy and the centre of a circle of correspondents, as well as Descartes' intellectual patron (see Mersenne, M.). Through his voluminous correspondence with Mersenne, Descartes remained connected to all the intellectual currents in Europe, wherever he was to live in later years. An important event in this period took place at a

gathering at the home of the Papal Nuncio in Paris in 1627 or 1628, where Descartes, responding to an alchemical lecture by one M. Chandoux, took the occasion to present his own ideas, including his ‘fine rule, or natural method’ and the principles on which his own philosophy was based (letter to Villebressieu, summer 1631; Descartes 1984-91 vol 3: 32). This attracted the attention of the Cardinal Bérule, who in a private meeting, urged Descartes to develop his philosophy.

In spring 1629 Descartes left Paris and moved to the Low Countries, where he set his methodological writing aside and began his philosophy in earnest. The winter of 1629-30 was largely occupied with the composition of a metaphysical treatise, which, as we shall later see, represents the foundations of his philosophy. The treatise is now lost, but Descartes told Mersenne that it had tried to ‘prove the existence of God and of our souls when they are separated from the body, from which follows their immortality’ (letter to Mersenne, 25 November 1630; Descartes 1984-91 vol 3: 29). This was followed by the drafting of *Le Monde (The World)*, Descartes’ mechanist physics and physiology, a book intended for publication. In the first part, also called the *Traité de la lumière (Treatise on Light)*, Descartes begins with a general account of the distinction between a sensation and the motion of tiny particles of different sizes and shapes that is its cause, followed by an account of the foundations of the laws of nature. After then positing an initial chaos of particles in motion (not *our* cosmos, but one made by God in some unused corner of the world), Descartes argues that by means of the laws of nature alone, this cosmos will sort itself into planetary systems, central suns around which swirl vortices of subtle matter which carry planets with them. He concludes the *Traité de la lumière* with an account of important terrestrial phenomena, including gravity, the tides and light, showing how much like our cosmos this imaginary mechanist cosmos will appear. The second part, the *Traité de l’homme (Treatise on Man)*, begins abruptly by positing that God made a body that looks exactly like ours, but which is merely a machine. Presumably missing - or never written - is a transition between the two treatises that shows how by the laws of nature alone this human body could arise in our world. (This part of the argument is noted in Part V of the later *Discourse on the Method*.) In the text that we now have, Descartes then went on to argue that all phenomena that pertain to life (thought aside) can arise in this body in a purely mechanical way, including nutrition and digestion, the circulation of blood, the movement of the muscles and the transmission of sensory information to the brain.

By 1633 Descartes had in hand a relatively complete version of his philosophy, from method, to metaphysics, to physics and biology. But in late 1633, he heard of the condemnation of Galileo’s Copernicanism in Rome, and cautiously decided not to publish his *World*, which was evidently Copernican (see Galileo Galilei). Indeed, he first decided never to publish anything at all. But the despair did not last. Between 1634 and 1636, Descartes collected some of the material he had been working on, and prepared three essays for publication, the *Géométrie*, the *Météors* and the *Dioptrique*. These scientific essays were preceded by a general introduction, the *Discours de la méthode pour bien conduir sa raison et chercher la vérité dans les sciences (Discourse on the Method for Properly Conducting Reason and Searching for Truth in the Sciences)*. The *Discourse* presents itself as autobiography, an account of the path the young author (the book was published anonymously) followed in his discoveries, including a summary of his method (Part II), of his early metaphysical speculations (Part IV) and of the programme of *The World* (Part V). In the scientific essays, Descartes presented some of his most striking results, hiding the foundational elements (such as his apparent Copernicanism and his rejection of scholastic form and matter) that would be most controversial.

While not uncontroversial, the *Discourse* and *Essays* were very successful, and induced Descartes to continue his programme for publishing his philosophy. The next work to appear was the *Meditationes (Meditations)* of 1641, which included an extensive selection of objections to the *Meditations* from various scholars in learned Europe, including Hobbes, Gassendi, Arnauld, and Mersenne himself, along with Descartes’ responses, a total of seven sets in all (these are cited in this entry as the *First Objections*, *Second Replies*, and so on). This was followed in 1644 by the publication of the *Principia Philosophiae (Principles of Philosophy)* in which, after a review of his metaphysics, Descartes gives an exposition of his physics adapted and expanded from *The World*. French translations of the *Meditations* and the *Principles* done by others, but with important variants from the original Latin (presumably introduced by Descartes himself), appeared in 1647.

By the late 1630s, Descartes’ work had entered the Dutch universities, and was taught at the University of Utrecht by Henricus Reneri and, following him, by Henricus Regius. Descartes’ un-Aristotelian views called down the wrath of Gisbertus Voëtius, who started a pamphlet war against Descartes and Regius that raged for some time.

Descartes supported Regius, and gave him advice as to how to respond and contain the affair. Eventually, however, Descartes broke with him when Regius wrote and in 1646 published his *Fundamenta physices*, about which Descartes had severe reservations. Regius responded with a broadsheet, a kind of summary of his main theses, emphasizing their differences. Descartes, in turn, responded in 1648 with the *Notae in programma quoddam (Comments on a Certain Broadsheet)*. There was a similar incident in Leiden, where Descartes had disciples (François du Ban, Adriaan Heereboord) as well as an influential enemy (Revius).

In the late 1640s Descartes was working on drafting and publishing more of his philosophy. Two additional parts of the *Principles* were planned, extending the work to cover elements of human biology. While notes remain in the form of an incomplete treatise on the human body (*La description du corps humain* - *Description of the Human Body*) and on the foetus (*Prima cogitationes circa generationem animalium* - *First Thoughts on the Generation of Animals*), the larger work was never finished. There are also important works concerning morals and moral psychology dating from these years. Some of this material is found in the letters to the Princess Elisabeth of Bohemia, with whom he had a long and important correspondence, starting in 1643. Descartes' account of the passions is found in the last work he published in his lifetime, the short *Passions de l'âme (Passions of the Soul)*, which appeared in 1649.

With the exception of a few short trips to Paris in 1644, 1647 and 1648, Descartes remained in the Low Countries until October 1649, when he was lured to Stockholm to be a member of the court of Queen Christina. There he fell ill in early 1650, and died on 11 February of that year.

2 The programme

Descartes' thought developed and changed over the years. But even so, there are a number of threads that run through it. Like most of his lettered contemporaries, Descartes was educated in a scholastic tradition that attempted to combine Christian doctrine with the philosophy of Aristotle. Indeed, at La Flèche, where he first learned philosophy, Aristotle as interpreted by Aquinas was at the centre of the curriculum. What he learned was an interconnected system of philosophy, including logic, physics, cosmology, metaphysics, morals and theology.

On his own account, Descartes rejected the Aristotelian philosophy as soon as he left school. From the notes Beeckman took on their conversations, it is probable that what dissatisfied him most in what he had been taught was natural philosophy. For an Aristotelian, the understanding of the natural world was grounded in a conception of body as composed of matter and form. Matter was that which remained constant even during the generation and corruption of bodies of different kinds, and that which all bodies of all sorts have in common; form was that which was responsible for the characteristic properties of particular sorts of bodies. For example, form was to explain why earth falls and tends to be cold, and why fire rises and tends to be hot. In contrast, though he came to reject Beeckman's rather strict atomism, Descartes seems to have been attracted to the kind of mechanistic view of the world that his mentor espoused. Descartes held from then on that the manifest properties of bodies must be explained in terms of the size, shape and motion of the tiny parts that make them up, and rejected the appeal to innate tendencies to behaviour that lay at the foundation of the Aristotelian view (see Aristotle §10).

But even though he rejected much of the philosophy of the schools, there was one element that remained with him: like his teachers at La Flèche, Descartes always held that knowledge has a kind of systematic coherence. In Rule 1 of the *Rules* Descartes wrote that 'everything is so interconnected that it is far easier to learn all things together than it is to separate one from the others… All [sciences are] connected with one another and depend upon one another'. Later, when he read Galileo's *Two New Sciences* (1638), Descartes dismissed the Italian scientist because his work lacked that kind of coherence (letter to Mersenne, 11 October 1638; Descartes 1984-91 vol 3: 124-8). His own project was to build his own interconnected system of knowledge, a system comprising an account of knowledge, a metaphysics, a physics and other sciences. This ambition is summarized in one of his last writings, the Preface to the French edition of the *Principles*, where he wrote that 'all philosophy is like a tree, whose roots are metaphysics, whose trunk is physics, and whose branches, which grow from this trunk, are all of the other sciences, which reduce to three principle sciences, namely medicine, mechanics, and morals'. In this way, Descartes saw himself as reconstituting the Aristotelian-Christian synthesis of the scholastics, grounded not in a natural philosophy of matter and form, but in a mechanist conception of body, where everything is to be explained in terms of size, shape and motion.

Certain important features of the Cartesian programme are worth special mention. The Aristotelian-Christian synthesis is founded in a variety of kinds of authority: the authority of the senses, the authority of ancient texts and the authority of his teachers. Descartes wanted to ground his thought in himself alone, and in the reason that God gave him. Since, Descartes claimed, reason gives us genuine certainty, this means that true knowledge is certain. In Rule 3 of the *Rules* he wrote that 'concerning things proposed, one ought to seek not what others have thought, nor what we conjecture, but what we can clearly and evidently intuit or deduce with certainty; for in no other way is knowledge acquired'. The rejection of the authority of the senses, texts and teachers shaped Descartes' thought in fundamental ways. Because of it, his philosophical system began with the Cogito Argument, which establishes the self as the starting-place of knowledge. Moreover, his two most influential works, the *Discourse* and the *Meditations*, were written in the first person so as to *show* the reader how Descartes did or might have come to his own state of knowledge and certainty, rather than *telling* readers what they are to believe, and thus setting himself up as an authority in his own right. Despite his rejection of authority, however, Descartes always claimed to submit himself to the authority of the Church on doctrinal matters, separating the domain of revealed theology from that of philosophy.

Another important feature of Descartes' tree of knowledge was its hierarchical organization. Throughout his career he held firmly to the notion that the interconnected body of knowledge that he sought to build has a particular order. Knowledge, for Descartes, begins in metaphysics, and metaphysics begins with the self. From the self we arrive at God, and from God we arrive at the full knowledge of mind and body. This, in turn, grounds the knowledge of physics, in which the general truths of physics (the nature of body as extension, the denial of the vacuum, the laws of nature) ground more particular truths about the physical world. Physics, in turn, grounds the applied sciences of medicine (the science of the human body), mechanics (the science of machines) and morals (the science of the embodied mind).

3 Method

Before beginning an account of the individual parts of Descartes' tree of knowledge, it is necessary to discuss his method. Method was the focus of his earliest philosophical writing, the *Rules*, and appeared prominently in his first published writing, the *Discourse on the Method*. But what exactly that method was is somewhat obscure.

In the second part of the *Discourse*, the method is presented as having four rules: (1) 'never to accept anything as true if I did not have evident knowledge of its truth: that is, carefully to avoid precipitate conclusions and preconceptions'; (2) 'to divide each of the difficulties I examined into as many parts as possible'; (3) 'to direct my thoughts in an orderly manner, by beginning with the simplest and most easily known objects in order to ascend little by little… to knowledge of the most complex'; and (4) 'throughout to make enumerations so complete and reviews so comprehensive, that I could be sure of leaving nothing out'. Given the general nature and apparent obviousness of these rules, it is not surprising that many of Descartes' contemporaries suspected him of hiding his *real* method from the public.

But Descartes' account of the method in the *Rules* is somewhat fuller. In Rule 5 he says: 'We shall be following this method exactly if we first reduce complicated and obscure propositions step by step to simpler ones, and then, starting with the intuition of the simplest ones of all, try to ascend through the same steps to a knowledge of all the rest'. This method is illustrated with an example in Rule 8. There Descartes considers the problem of the anaclastic line, the shape of a lens which will focus parallel lines to a single point. The first step in the solution of the problem, Descartes claims, is to see that 'the determination of this line depends on the ratio of the angles of refraction to the angles of incidence'. This, in turn, depends on 'the changes in these angles brought about by differences in the media'. But 'these changes depend on the manner in which a ray passes through the entire transparent body, and knowledge of this process presupposes also a knowledge of the nature of the action of light'. Finally, Descartes claims that this last knowledge rests on our knowledge of 'what a natural power in general is'. This last question can, presumably, be answered by intuition alone, that is, a purely rational apprehension of the truth of a proposition that has absolute certainty. Once we know what the nature of a natural power is, we can, Descartes thought, answer one by one all the other questions raised, and eventually answer the question originally posed, and determine the shape of the lens with the required properties. These successive answers are to be connected deductively (in a way outlined in the *Rules*) with the first intuition, so that successive answers follow intuitively from the first intuition.

The example of the anaclastic line suggests that Descartes' method proceeds as follows. One starts with a particular question, q_1. The reductive moment in the method then proceeds by asking what we have to know in order to answer the question originally posed. This leads us from q_1 to another question, q_2, whose answer is presupposed in order for us to be able to answer q_1; it is in this sense that q_1 is said to be reduced to q_2. This reductive process continues until we reach a question whose answer we are capable of knowing through intuition, say q_n. At that point, we begin what might be called the constructive moment of the method, and successively answer the questions we have posed for ourselves, using the answer to q_n to answer q_{n-1}, the answer to q_{n-1} to answer q_{n-2}, and so on until we arrive at q_1, the question originally posed, and answer that.

Understood in this way, the method has some very interesting properties. First, it results in knowledge that is completely certain. When we follow this method, the answer to the question originally posed is grounded in an intuition; the answers to the successive questions in the series are to be answered by deducing propositions from propositions that have been intuitively grasped as well. Second, the method imposes a certain structure on knowledge. As we follow the series of questions that constitute the reductive step of the method, we proceed from more specific questions to more general, from the shape of a particular lens to the law of refraction, and ultimately to the nature of a natural power. The answers that are provided in the constructive stage follow the opposite path, from the metaphysically more general and more basic to the more specific.

The *Rules* was written over a long period of time, and there are numerous strata of composition evident in the work as it survives. In a passage from Rule 8 that is probably in one of the last strata of composition, Descartes raises a problem for the method itself to confront, indeed the *first* problem that it should confront: 'The most useful inquiry we can make at this stage is to ask: What is human knowledge and what is its scope?… This is a task which everyone with the slightest love of truth ought to undertake at least once in life, since the true instruments of knowledge and the entire method are involved in the investigation of the problem'. While it is not entirely clear what Descartes had in mind here, it is not implausible to interpret him as raising the problem of the justification of intuition itself, the epistemological foundation of the method. In framing the method in the *Rules*, Descartes takes for granted that he has a faculty, intuition, by which he is capable of grasping truth in some immediate way, and what he knows by intuition is worthy of trust. But why *should* we trust intuition? This, in essence, is one of the central questions in the *Meditations*, where Descartes argues that whatever we perceive clearly and distinctly is true.

Method was a central concern of Descartes' earlier writings, in both the *Rules* and the *Discourse*. In later writings it seemed to play little explicit role in his thought, but the hierarchical structure of knowledge with which the method is closely connected - the idea that knowledge is grounded in a structure of successively more metaphysically basic truths, ultimately terminating in an intuition - remained basic to his thought. In his later work, that ultimate intuition is not the nature of a natural power, as it was in the anaclastic line example, but the intuition that establishes the existence of the knowing subject, the Cogito Argument.

4 Doubt and the quest for certainty

In the *Rules for the Direction of the Mind*, Rule 2 reads: 'We should attend only to those objects of which our minds seem capable of having certain and indubitable cognition'. While, as we shall later see, Descartes seemed to relax this demand somewhat in his later writings, the demand for certainty was prominent throughout many of his writings. Historically, this can be seen as a reaction against important sceptical currents in Renaissance thought, the so-called 'Pyrrhonist Crisis'. In the face of the rapidly expanding boundaries of the European world in the sixteenth century, from new texts to new scientific discoveries to the discoveries of new worlds, contradictions and tensions in the intellectual world abounded, making it more and more attractive to hold, with the classical sceptics, that real knowledge is simply beyond the ability of human beings to acquire (see Scepticism, Renaissance; Pyrrhonism). Against this, Descartes asserted that real, certain knowledge is possible; though his name is associated with scepticism, it is as an opponent and not an advocate.

But though certainty was central to Descartes, the path to certainty begins with doubt. In Meditation I, entitled 'What can be called into doubt', Descartes says that 'I realised that it was necessary, once in the course of my life, to demolish everything completely and start again right from the foundations if I wanted to establish anything at all in the sciences that was stable and likely to last'. Following that, he presents a series of three sceptical arguments designed to eliminate his current beliefs in preparation for replacing them with certainties. The strategy is to

undermine the beliefs, not one by one but by undermining ‘the basic principles’ on which they rest. While at least some of these arguments can be found in versions in the *Discourse* and in other writings by Descartes, they receive their fullest exposition in the *Meditations*.

The first argument is directed at the naïve belief that everything learned via the senses is worthy of belief. Against this Descartes points out that ‘from time to time I have found that the senses deceive, and it is prudent never to trust completely those who have deceived us even once’. The second, the famous dream argument, is directed against the somewhat less naïve view that the senses are at least worthy of belief when dealing with middle-sized objects in our immediate vicinity: ‘A brilliant piece of reasoning! As if I were not a man who sleeps at night… I plainly see that there are never any sure signs by means of which being awake can be distinguished from being asleep’. But even if I doubt the reliability of what the senses seem to be conveying to me right now, Descartes supposes, the dream argument still leaves open the possibility that there are some general truths, not directly dependent on my present sensations, that I can know. Descartes replies to this with his deceiving God argument.

This complex argument has two horns. Descartes first supposes ‘the long-standing opinion that there is an omnipotent God who made me the kind of creature that I am’. Because God is omnipotent, he might have made me in such a way that I go wrong in even the simplest and most evident beliefs that I have - for example, that $2 + 3 = 5$, or that a square has four sides. Though God is thought to be good, the possibility that I am so deeply prone to error seems as consistent with his goodness as the fact that I go wrong even occasionally, at least at this stage of the investigation. But what if there is no God, or what if I arose by ‘fate or chance or a continuous chain of events, or by some other means’? In this case, Descartes argues, the less powerful my original cause, ‘the more likely it is that I am so imperfect as to be deceived all the time’.

With this, the sceptical arguments of Meditation I are complete: ‘I am finally compelled to admit that there is not one of my former beliefs about which a doubt may not properly be raised’. But, Descartes notes, ‘my habitual opinions keep coming back’. It is for that reason that Descartes posits his famous evil genius: ‘I will suppose therefore that not God, who is supremely good and the source of truth, but rather some evil genius of the utmost power and cunning has employed all his energies in order to deceive me’. The evil genius (sometimes translated as the ‘evil demon’) is introduced here not as a separate argument for doubt, but as a device to help prevent the return of the former beliefs called into doubt.

These arguments have a crucial function in Descartes’ project. As he notes in the introductory synopsis of the *Meditations*, these arguments ‘free us from all our preconceived opinions, and provide the easiest route by which the mind may be led away from the senses’. In this way the sceptical doubt of Meditation I prepares the mind for the certainty to which Descartes aspired. But in the *Third Replies*, responding to criticisms from Hobbes, Descartes notes two other roles that the sceptical arguments play in his thought. Descartes remarks that they are introduced ‘so that I could reply to them in the subsequent Meditations’. As considered below, the deceiving God argument is answered in Meditations III and IV, and the dream argument is answered in the course of his discussion of sensation in Meditation VI. (Since Descartes, quite rightly, continued to maintain that sensation is not entirely trustworthy as a guide to how things really are, the first sceptical argument is never fully answered, though in Meditation VI he carefully sets out the conditions under which we can trust the senses.) Finally, he notes that the arguments are there as a kind of standard against which he can measure the certainty of his later conclusions: ‘I wanted to show the firmness of the truths which I propounded later on, in the light of the fact that they cannot be shaken by these metaphysical doubts’. In all these ways, Descartes presented himself as addressing the sceptic, and defending a kind of dogmatic philosophy.

5 The Cogito Argument

Descartes’ philosophy begins in doubt. The first step towards certainty, the Archimedean point from which the whole structure will grow, is the discovery of the existence of the self. At the beginning of Meditation II, reflecting on the evil genius posited at the end of Meditation I, Descartes observes: ‘Let him deceive me as much as he can, he will never bring it about that I am nothing so long as I think that I am something… I must finally conclude that this proposition, *I am*, *I exist*, is necessarily true whenever it is put forward by me or conceived in my mind’. In the earlier *Discourse* (Part IV) and the later *Principles of Philosophy* (Part I §7), this proposition has the more familiar form, ‘I am thinking, therefore I exist,’ or, ‘ego cogito, ergo sum,’ in its Latin formulation. Here, it is called the Cogito Argument.

There is considerable discussion about how exactly Descartes thought this argument functions. There are two strains of interpretation that derive directly from his texts. In the *Second Replies*, Descartes observes that 'when we become aware that we are thinking things, this is a primary notion which is not derived by means of any syllogism'. This suggests that the Cogito Argument is known immediately by direct intuition. In the *Principles* (Part I §10), however, Descartes notes that before knowing the Cogito, we must grasp not only the concepts of thought, existence and certainty, but also the proposition that 'it is impossible that that which thinks should not exist'. This suggests that the Cogito *is* a kind of syllogism, in which I infer my existence from the fact that I am thinking, and with the premise that whatever thinks must exist. Recent analytic philosophers have also been attracted to the Cogito, trying to understand its obvious allure through speech act theory and theories of demonstratives (Hintikka 1967; Markie 1992). These accounts, however, are distant from anything that Descartes himself conceived.

There is also some confusion about what the conclusion of the Cogito Argument is supposed to be. In the body of Meditation II, Descartes clearly establishes the existence of the self as a thinking thing or a mind. But the title of Meditation II, 'The nature of the human mind, and how it is better known than the body' suggests that Descartes believed that he had established that the nature of the human mind is thought. Further still, in parallel texts in the *Discourse* (Part IV) and the *Principles* (Part I §7-8), Descartes suggests that the Cogito establishes the existence of a thinking substance distinct from the body, though in the text of Meditation II, this seems to be denied.

Though most closely associated with Descartes, the Cogito Argument may not be altogether original. A number of Descartes' contemporaries, both during his life and afterwards, noticed the connection between the Cogito and similar formulations in Augustine (see Augustine §2). However, what was important to Descartes about the Cogito is the foundational role it plays in his system. For Descartes, it is 'the first thing we come to know when we philosophise in an orderly way' (*Principles*: Part I §7). Common sense might think that the physical world of bodies, known through sensation, is more accessible to us than is the mind, a thinking thing whose existence is established, even though we have rejected the senses. But, as Descartes argues in Meditation II using the example of a piece of wax, despite our prejudices, bodies are not conceived through the senses or the imagination but through the same process of purely intellectual conception that gives us the conception of ourselves as thinking things. Furthermore, knowledge of the external world is less certain than knowledge of the mind, since whatever thought could lead us to a probable belief in the existence of bodies will lead us to believe in the existence of the self with certainty.

The project, then, is to build the entire world from the thinking self. It is important here that it is not just the mind that is the foundation, but *my* mind. In this way, the starting place of philosophy for Descartes was connected with the rejection of authority that is central to the Cartesian philosophy. In beginning with the Cogito, we build a philosophy detached from history and tradition.

6 God

The next stage in the system, as outlined in the *Meditations*, seeks to establish that God exists. In his writings, Descartes made use of three principal arguments. The first (at least in the order of presentation in the *Meditations*) is a causal argument. While its fullest statement is in Meditation III, it is also found in the *Discourse* (Part IV) and in the *Principles* (Part I §§ 17-18). The argument begins by examining the thoughts contained in the mind, distinguishing between the formal reality of an idea and its objective reality. The formal reality of any thing is just its actual existence and the degree of its perfection; the formal reality of an idea is thus its actual existence and degree of perfection as a mode of mind. The objective reality of an idea is the degree of perfection it has, considered now with respect to its content. (This conception extends naturally to the formal and objective reality of a painting, a description or any other representation.) In this connection, Descartes recognized three fundamental degrees of perfection connected with the capacity a thing has for independent existence, a hierarchy implicit in the argument of Meditation III and made explicit in the *Third Replies* (in response to Hobbes). The highest degree is that of an infinite substance (God), which depends on nothing; the next degree is that of a finite substance (an individual body or mind), which depends on God alone; the lowest is that of a mode (a property of a substance), which depends on the substance for its existence. Descartes claims that 'it is manifest by the natural light that there must be at least as much reality in the efficient and total cause as in the effect of that cause'. From that he infers that there must be as much *formal* reality in the cause of an idea as there is *objective* reality in the idea itself.

This is a bridge principle that allows Descartes to infer the existence of causes from the nature of the particular ideas that are in the mind, and thus are effects of some causes or another. In Meditation III, Descartes discusses various classes of ideas, one by one, and concludes that, as a finite substance, he can conceivably be the cause of all the ideas he has in his mind except for one: the idea of God. Since the idea of God is an idea of something that has infinite perfection, the only thing that can cause that idea in my mind is a thing that formally (actually) has the perfection that my idea has objectively - that is, God himself.

Descartes used two other arguments for the existence of God in his writings. In Meditation III, following the causal argument, he offers a version of the cosmological argument for those who, still blinded by the senses, may be reluctant to accept the bridge principle that his causal argument requires. (Versions of this argument are also found in *Discourse* Part IV, and in *Principles* Part I §§20-1.) This argument begins with the author's own existence, as established in Meditation II. But, the author might ask, what could have created me? It will not do, Descartes argues, to suggest that I have been in existence always, and thus I do not need a creator, since it takes as much power to sustain me from moment to moment as it does to create me anew. I could not have created myself because then I would have been able to give myself all the perfections that I so evidently lack. Furthermore, if I could create myself, then I could also sustain myself, which I do not have the power to do; being a thinking thing, if I had such a power, I would be aware of having it. My parents cannot be my creators, properly speaking, since they have neither the ability to create a thinking thing (which is all I know myself to be at this stage of the *Meditations*), nor to sustain it once created. Finally, I could not have been created by another creature of lesser perfection than God, since I have an idea of God, an idea I could not acquire from a lesser being. (Here one suspects that this cosmological argument really collapses into the first causal argument.) From this Descartes concludes 'that the mere fact that I exist and have within me an idea of a most perfect being… provides a very clear proof that God indeed exists'.

These first two arguments for the existence of God play a central role in the validation of reason, as discussed below. But after reason has been validated on theological grounds, Descartes presents in Meditation V a version of the ontological argument (see God, arguments for the existence of §§2-3). After reflecting on the basis of geometric reasoning, the fact that 'everything which I clearly and distinctly perceive to belong to that thing really does belong to it', Descartes concludes that this applies to the idea of God as well. Hence he concludes that 'it is quite evident that existence can no more be separated from the essence of God than the fact that its three angles equal to two right angles can be separated from the essence of a triangle, or than the idea of a mountain can be separated from the idea of a valley'. Though apparently circular in so far as its validity seems to depend on the prior arguments for the existence of God, it is not; Descartes' point is that 'even if it turned out that not everything on which I have meditated in these past days is true, I ought still to regard the existence of God as having at least the same level of certainty as I have hitherto attributed to the truths of mathematics'. As with the other two arguments, Descartes' ontological argument is also found in the *Discourse* (Part IV) and in the *Principles* (Part I §§14-16); indeed, in the *Principles* it is the first argument he gives.

As noted above, the existence of God plays a major role in the validation of reason. But it also plays a major role in two other parts of Descartes' system. As we shall later see in connection with Descartes' physics, God is the first cause of motion, and the sustainer of motion in the world. Furthermore, because of the way he sustains motion, God constitutes the ground of the laws of motion. Finally, Descartes held that God is the creator of the so-called eternal truths. In a series of letters in 1630, Descartes enunciated the view that 'the mathematical truths which you call eternal have been laid down by God and depend on Him entirely no less than the rest of His creatures' (letter to Mersenne, 15 April 1630; Descartes 1984-91 vol 3: 23), a view that Descartes seems to have held into his mature years. While it never again gets the prominence it had in 1630, it is clearly present both in correspondence (for example, letter to Arnauld, 29 July 1648; Descartes 1984-91 vol 3: 358-9) and in published writings (for example, in the *Sixth Responses*).

Various commentators have proposed that Descartes was really an atheist, and that he includes the arguments for the existence of God as window dressing. While this is not impossible, the frequent appeal to God in philosophical contexts, both in private letters and in published work, suggests that it is rather unlikely.

7 The validation of reason

With the existence of God established, the next stage in Descartes' programme is the validation of reason. At the

beginning of Meditation III, before proving God's existence, Descartes notes that the uncertainty that remains is due only to the fact that the meditator does not know whether or not there is a God and, if there is, if he can be a deceiver. This suggests that all one must do to restore reason and defeat the third and most general sceptical argument presented in Meditation I is to prove that there is a benevolent God. And at the end of Meditation III, after two proofs for the existence of God, Descartes concludes directly that this God 'cannot be a deceiver, since it is manifest by the natural light that all fraud and deception depend on some defect'. But this is not enough. In the course of the deceiving-God argument of Meditation I, Descartes notes that if some deception is consistent with divine benevolence, then total deception would be as well. Since it is undeniable that we do make mistakes from time to time, and are thus deceived, this raises a problem for Descartes: what, if anything, does God's benevolence and veracity guarantee?

Descartes answers this question by way of an account of error in Meditation IV. Roughly speaking, the mistakes I make are due to myself and my (improper) exercise of my free will, while the truths I come to know are because of the way God made me. More exactly, Descartes asserts that judgments depend on two faculties of the mind, 'namely, on the faculty of knowledge [or intellect] which is in me, and on the faculty of choice or freedom of the will'. A judgment is made when the will assents to an idea that is in the intellect. But the intellect is finite and limited in the sense that it does not have ideas of all possible things. On the other hand, the will is indefinite in its extent, Descartes claims: 'It is only the will or freedom of choice which I experience within me to be so great that the idea of any greater faculty is beyond my grasp'. It is in our free will that we most resemble God. In certain circumstances, Descartes held, 'a great light in the intellect is followed by a great inclination in the will', and in this way the intellect determines the will to assent. This, he thought, is a proper use of the will in judgment. In this situation, where the intellect determines the will to assent, Descartes talks of our having a clear and distinct perception of a truth. In this case, God has made us in such a way that we cannot but assent. (Clear and distinct perceptions are very close to what he calls 'intuitions' in the *Rules*, as discussed above.) But because the will has a greater extent than the intellect, and is not restrained by it, sometimes things outside the intellect move the will to assent. This is where error enters: 'The scope of the will is wider than that of the intellect; but instead of restricting it within the same limits, I extend its use to matters which I do not understand. Since the will is indifferent in such cases, it easily turns aside from what is true and good, and this is the source of my error and sin.' In this way, I am responsible for error by extending my will beyond where it belongs. God can in no way be held accountable for my mistakes any more than he can be responsible for my sins. I cannot reproach my maker for not having given me more ideas in the intellect than I have, nor can I fault him for having made me more perfect by giving me a free will. But as a result of a limited intellect and a free will, it is possible for me both to make mistakes and to sin.

As a result of this analysis of error, Descartes is able, in Meditation IV to assert his famous principle of clear and distinct perception, an epistemological principle to replace the principles that were rejected as a result of the sceptical arguments of Meditation I: 'If I simply refrain from making a judgement in cases where I do not perceive the truth with sufficient clarity and distinctness, then it is clear that I am behaving correctly and avoiding error. But if in such cases I either affirm or deny, then I am not using my free will correctly'. With this, reason is validated, and the deceiving-God argument answered. Yet, this does not end Descartes' engagement with the sceptical arguments of Meditation I, and in Meditation VI he also addresses the question of the reliability of the senses, presents a limited validation of sensory knowledge, and answers the dream argument.

The validation of reason, central as it is to Descartes' project in the *Meditations*, has one apparent flaw: it seems to be circular. The validation of reason in Meditation IV depends on the proof of the existence of God which, in turn, depends on the proof of the existence of the self as a thinking thing. But evidently we must assume that clear and distinct perceptions are trustworthy in order to trust the Cogito and the proofs for the existence of God that ground the validation of reason - the so-called 'Cartesian Circle'. Two of the objectors to the *Meditations* noticed this point, and elicited responses from Descartes, in the *Second* and the *Fourth Replies*. Descartes' answer is not altogether clear. In the *Second Replies* he remarks, in answer to one such objection, that 'when I said that we can know nothing for certain until we are aware that God exists, I expressly declared that I was speaking only of knowledge of those conclusions' deduced by long arguments, and not of 'first principles', such as the Cogito Argument. This suggests that Descartes would exempt immediately intuitable (self-evident) propositions from the scope of the doubt of Meditation I, and use them as tools for establishing the premises of the argument that leads to

the validation of reason in Meditation IV. There are serious problems with this approach. For one, it seems arbitrary to exempt self-evident propositions from the scope of doubt. Such propositions would seem to fall quite naturally among those most obvious of things that Descartes calls into doubt there; if God could create me in such a way that I go wrong when I add two and three, he could create me in such a way that I go wrong with any other self-evident belief. Furthermore, even if those propositions that are immediately evident are outside the scope of doubt, Descartes' proofs for the existence of God, necessary premises of his validation of reason, are not self-evident. These apparent problems might be either weaknesses in Descartes' response, or reasons to doubt that we have understood Descartes correctly in his responses.

The problem of circularity and the obvious problems in Descartes' apparent answer have elicited numerous examinations of the issue in the commentary literature. It is not clear just what Descartes' own solution was, nor whether or not there is a good response to the Cartesian Circle. But whatever the answer, the problem is not a superficial oversight on Descartes' part. It is a deep philosophical problem that will arise in some form or another whenever one attempts a rational defence of reason.

8 Mind and body

One of Descartes' most celebrated positions is the distinction between the mind and the body. Descartes did not invent the position. It can be found in various forms in a number of earlier thinkers. It is a standard feature of Platonism and, in a different form, is common to most earlier Christian philosophers, who generally held that some feature of the human being - its mind or its soul - survives the death of the body (see Plato §13). But the particular features of Descartes' way of drawing the distinction and the arguments that he used were very influential on later thinkers.

There are suggestions, particularly in the *Discourse* (Part IV) and in the *Principles* (Part I §§7-8) that the distinction between mind and body follows directly from the Cogito Argument, as discussed above. However, in the *Meditations* Descartes is quite clear that the distinction is to be established on other grounds. In Meditation VI he argues as follows: I have a clear and distinct idea of myself as a thinking non-extended thing, and a clear and distinct idea of body as an extended and non-thinking thing. Whatever I can conceive clearly and distinctly, God can so create. So, Descartes argues, the mind, a thinking thing, can exist apart from its extended body. And therefore, the mind is a substance distinct from the body, a substance whose essence is thought.

Implicit in this argument is a certain conception of what it means to be a substance, a view made explicit in the *Principles* (Part I §51) which defines a substance as 'nothing other than a thing which exists in such a way as to depend on no other thing for its existence', no other thing but God, of course. In so far as the mind can exist independently of the body, it is a substance on this definition. (God is the third kind of substance, along with mind and body, though because of his absolute independence, he is a substance in a somewhat different sense.) On Descartes' metaphysics, each substance has a principal attribute, an attribute that characterizes its nature. For mind it is thought, and for body it is extension. In addition, substances have modes, literally ways of instantiating the attributes. So, for Descartes, particular ideas, particular volitions, particular passions are modes of mind, and particular shapes, sizes and motions are modes of body.

Descartes' conception of mind and body represents significant departures from the conceptions of both notions in the late scholastic thought in which he was educated. For the late scholastics, working in the Aristotelian tradition, body is composed of matter and form. Matter is that which remains constant in change, while form is that which gives bodies the characteristic properties that they have. For Descartes, however, all body is of the same kind, a substance that contains only geometric properties, the objects of geometry made concrete. The characteristic properties of particular forms of body are explained in terms of the size, shape and motion of its insensible parts (see §11 below). For the late scholastics, the mind is connected with the account of life. On the Aristotelian view, the soul is the principle of life, that which distinguishes a living thing from a dead thing; it is also taken to be the form that pertains to the living body. The mind is the rational part of the soul, that which characterizes humans, and not usually considered a genuine substance, though by most accounts, with divine aid, it can survive the death of the body (see Nous; Psychē). For Descartes, the majority of the vital functions are explained in terms of the physical organization of the organic body. The mind, thus, is not a principle of life but a principle of thought. It involves reason, as does the rational soul of the Aristotelians, but it also involves other varieties of thought, which pertain to other parts of the Aristotelian soul (see Aristotle §17). Furthermore, it is a genuine substance, and

survives the death of the body naturally and not through special divine intervention.

Mind and body are distinct because they can exist apart from one another. However, in this life, they do not. In Meditation VI Descartes observed: 'Nature also teaches me, by these sensations of pain, hunger, thirst and so on that I am not merely present in my body as a sailor is present in a ship, but that I am very closely and, as it were, intermingled with it, so that I and the body form a unit'. He sometimes went so far as to say that the human mind is the form of the human body, the only kind of form that he recognizes in nature, and that the human being - the union of a mind and a body - constitutes a genuine substance, though the context of these statements suggests that they may be made more for orthodoxy's sake than an expression of his own views (see, for example, the letter to Regius, January 1642 (Descartes 1984-91 vol 3: 208), where he is advising Regius on the best way to answer the attacks made by the more orthodox Aristotelian Gisbertus Voëtius in connection with the controversy at Utrecht.) But be that as it may, he was clearly committed to holding that the mind and the body are united. Some of his contemporaries found it difficult to understand how two such different substances could interact and be joined. Sometimes Descartes dismissed this objection by saying that it is no more difficult than understanding how form and matter unite for the Aristotelians, something that everyone learns at school (letter to Arnauld, 29 July 1648; Descartes 1984-91 vol 3: 358). But elsewhere, particularly in an important exchange of letters with the Princess Elisabeth of Bohemia, Descartes offered a different explanation, remarking that it is simply an empirical fact that they do unite and interact, something that we learn from everyday experience, and suggesting that just as we have innate notions that allow us to understand the notions of thinking and extended substance, we also have an innate notion that allows us to comprehend how mind and body interact, and how together they can constitute a unity (letters to Elisabeth, 21 May 1643 and 28 June 1643; Descartes 1984-91 vol 3: 217-20, 226-9).

According to Descartes, the mind is joined to the body in one specific place: the pineal gland, a single gland in the centre of the brain, between the two lobes. This is the spot in which interaction takes place. The mind has the ability to move the pineal gland, and by doing so, to change the state of the brain in such a way as to produce voluntary motions. Similarly, the sensory organs all transmit their information to the pineal gland and, as a result of that, sensation is transmitted to the attached mind. However, because of the interconnection of the parts that make up the organic body, by virtue of being connected to the pineal gland, the mind can properly be said to be connected with the body as a whole (*Passions*: §§30-2) (see Persons).

9 The external world and sensation

The argument for the distinction between mind and body in Meditation VI establishes the nature of body as extension, but it does not establish the real existence of the world of bodies outside of the mind. This is the focus of the last series of arguments in the *Meditations*. The argument begins in Meditation VI with the recognition that I have 'a passive faculty of sensory perception', which would be useless unless there was also an 'active faculty, either in me or in something else' which produces the ideas of sensation. Descartes has already established in Meditation IV that the mind has only two faculties - a passive faculty of perception, and the active faculty of will. Since it is passive, perception cannot be the source of my ideas of sensation, and since sensations are involuntary, they cannot be the product of my will. So, the ideas of sense must come from somewhere else. God 'has given me a great propensity to believe that they are produced by corporeal things', and no means to correct my error if that propensity is deceptive. So, Descartes concluded, God would be a deceiver if my sensory ideas come from anything but from bodies. This argument does not prove that everything we sense about bodies is reliable, but only that 'they possess all the properties which I clearly and distinctly understand, that is, all those which, viewed in general terms, are comprised within the subject-matter of pure mathematics'. (In the *Principles* Part II §1 there is also an argument for the existence of the external world, but it is somewhat different.)

The proof of the existence of the external world tells us that, in general, bodies are the causes of our sensations and it tells us, in general, what the nature of body is. But it does not seem to tell us much about what we can (and cannot) learn about specific bodies in the world around us in specific circumstances. These questions are addressed at the end of Meditation VI in a general discussion of the reliability of sensation, the most extensive such discussion in Descartes' writings. He argues there that the senses are given to me 'simply to inform the mind of what is beneficial or harmful for the composite of which the mind is a part; and to this extent they are sufficiently clear and distinct'. That is, while they cannot tell me anything about the real nature of things - that is for the intellect or reason to determine - they can inform me about specific features of my environment that relate to

maintaining the union of my mind and body. So, for example, when the senses tell us that some particular apples are red and others green, this can give us reliable information that some may be ripe (and thus nutritious) and others not, but it cannot tell us that the one is, in its nature, red, and the other really green. Similarly, when I feel a pain in my toe, this tells me that there is damage to my toe, not that there is something resembling the sensation that is actually in the toe. Even in this, the sensation may be misleading. As Descartes points out, people sometimes feel pain in limbs even after they have been amputated.

Given the nature of the extended body, and the causal process by which pains (and other sensations) are transmitted through the body to the pineal gland, where the non-extended mind is joined to the extended body, such misleading sensations are inevitable; similar sensations in the mind can be the result of very different causal processes in the body. For example, a sensation of pain-in-the-toe can be caused either by a change in the state of the toe itself, or by an appropriate stimulation of the nerve connecting the toe to the brain at any point between the two. But, Descartes claims, though sensation is fallible, 'I know that in matters regarding the well-being of the body, all my senses report the truth much more frequently than not'. Furthermore, I can use multiple senses and memory, together with the intellect, 'which has by now examined all the causes of error' in order to weigh the evidence of the senses and use it properly. And with this, Descartes is finally able to answer the dream argument of Meditation I. For my waking experience is interconnected in a way in which my dreaming experience is not; the things I see in waking life, unlike those in dreams, come to me through all my senses, and connect with my memory of other objects. I can use this interconnectedness of waking experience, together with my intellect and my knowledge of the causes of error, to sort out veridical sensations and distinguish them from the deceptive sensory experiences of dreams. Sometimes even my waking experiences will be deceptive, of course, but we are capable of determining specific circumstances in which the senses are worthy of our trust. And so, contrary to the original doubts raised by the dreaming argument in Meditation I, there is no general reason to reject waking experience as such.

Though subordinated to reason, sensation, cast into doubt in Meditation I, re-enters as a legitimate source of knowledge about the world by the end of Meditation VI.

10 Philosophical psychology and morals

Morality was a concern of Descartes' in a variety of texts. In the third part of his *Discourse* he presents what he calls a 'provisional morality', a morality to govern our behaviour while we are in the process of revising our beliefs and coming to certainty. In the tree of philosophy in the Preface to the French edition of the *Principles*, morals is listed as one of the fruits of the tree, along with medicine and mechanics. It is also a theme in the letters he exchanged with the Princess Elisabeth of Bohemia in the mid-1640s, together with another concern - the passions, what they are and, more importantly, how to control them. These themes are intertwined again in Descartes' last major work, the *Passions of the Soul* (1649).

In one of the letters that serves as a preface to the *Passions*, Descartes announces that he will treat the passions 'only as a natural philosopher [*en physicien*], and not as a rhetorician or even as a moral philosopher'. Accordingly, the bulk of the *Passions* is taken up with detailed accounts of what the passions are, and how they arise from the connection between the human body and the human mind. As Descartes conceived them, the passions are grouped with sensation and imagination, perceptions of the mind that arise from external impulses. In this respect, Descartes differed radically from the Aristotelian scholastic philosophers who attached the passions to the appetitive faculty rather than the perceptive. But though grouped with other perceptions, the ones that concern Descartes in this treatise are a special group of perceptions, 'those whose effects we feel as being in the soul itself, and for which we do not normally know any proximate cause to which we can refer them', those 'which are caused, maintained, and strengthened by some movement of the spirits' (*Passions*: §§25, 27). (The 'spirits' in question are the animal spirits, a fluid matter that played a major role in Descartes' biology.) The principal effect of the passions is to 'move and dispose the soul to want the things for which they prepare the body. Thus the feeling of fear moves the soul to want to flee, that of courage to want to fight' and so on (*Passions*: §40). As with sensations, the passions of the soul play a role in the preservation of the mind - body union: 'The function of all the passions consists solely in this, that they dispose our soul to want the things which nature deems useful for us, and to persist in this volition; and the same agitation of the spirits which normally causes the passions also disposes the body to make movements which help us to attain these things' (*Passions*: §52).

For the schoolmen, the passions pertained to the appetitive faculty, and were principally organized around a distinction between the ‘irascible’ and the ‘concupiscent’ appetites. Descartes, however, was attempting to fashion a conception of the passions based on a very different conception of the soul, one in which there is no distinction among appetites (*Passions*: §68). His categorization of the passions was based on a list of six primitive passions, which pertain to the perceptive rather than to the appetitive faculty: wonder, desire, love and hatred, joy and sadness - ‘all the others are either composed from some of these six or they are species of them’ (*Passions*:§69). Much of his attention in the short book is directed at accounts of what each of these basic passions is, what it feels like and its physiological causes and effects in the body, and how all the other passions can be understood in terms of the six basic ones.

But although Descartes presents himself as examining the passions ‘*en physicien*’, there is a moral dimension to the discussion as well. Part of the motivation for the examination of the passions is their control. While the passions, like everything given to us by God, can contribute to our well-being, they can also be excessive and must be controlled (*Passions*: §211). While the passions are not under our direct control, by understanding what they are and how they are caused we can learn indirect means for controlling them (*Passions*: §§45-50; 211). This, Descartes asserts, is the ‘chief use of wisdom, [which] lies in its teaching us to be masters of our passions and to control them with such skill that the evils which they cause are quite bearable, and even become a source of joy’ (*Passions*: §212). Important in this process is what Descartes calls *génénerosité*, best translated as ‘nobility’. *Générosité* is the knowledge that all that belongs to us, properly speaking, is our own free will, and the resolution to use it well, ‘that is, never to lack the will to undertake and carry out whatever one judges to be best’ (*Passions*: §53). Understood in this way, *générosité* is both a passion (an immediate feeling) and a virtue (‘a habit of the soul which disposes it to have certain thoughts’) (*Passions*: §§160-1). The person who has *générosité* ‘has very little esteem for everything that depends on others’, and as a result, Descartes claims, is able to control their passions (*Passions*:§156).

11 Physics and mathematics

To his contemporaries, Descartes was as well-known for his system of physics as he was for the metaphysical views that are now more studied. Indeed, as he indicates in the Preface to the French edition of the *Principles*, metaphysics constitutes the roots of the tree of philosophy, but the trunk is physics.

Descartes’ physics was developed in two main places. The earliest is in the treatise *Le Monde (The World)* which he suppressed when Galileo was condemned for Copernicanism in 1633, though summarized in Part V of the *Discourse*. Later, in the early 1640s, he presented much of the material in a more carefully worked-out form, in Parts II, III and IV of the *Principles*. Like the physical thought of many of his contemporaries, his physics can be divided into two parts - a general part, which includes accounts of matter and the general laws of nature, and a specific part, which includes an account of particular phenomena.

The central doctrine at the foundations of Descartes’ physics is the claim that the essence of body is extension (discussed in §8 above). This doctrine excludes substantial forms and any sort of sensory qualities from body. For the schoolmen there are four primary qualities (wet and dry, hot and cold) which characterize the four elements. For Descartes, these qualities are sensations in the mind, and only in the mind; bodies are in their nature simply the objects of geometry made real. Descartes also rejected atoms and the void, the two central doctrines of the atomists, an ancient school of philosophy whose revival by Gassendi and others constituted a major rival among contemporary mechanists. Because there can be no extension without an extended substance, namely body, there can be no space without body, Descartes argued. His world was a plenum, and all motion must ultimately be circular, since one body must give way to another in order for there to be a place for it to enter (*Principles* II: §§2-19, 33). Against atoms, he argued that extension is by its nature indefinitely divisible: no piece of matter in its nature indivisible (*Principles* II: §20). Yet he agreed that, since bodies are simply matter, the apparent diversity between them must be explicable in terms of the size, shape and motion of the small parts that make them (*Principles* II: §§23, 64) (see Leibniz, G.W. §4).

Accordingly, motion and its laws played a special role in Descartes’ physics. The essentials of this account can be found in *The World*, but it is set out most clearly in the *Principles*. There (*Principles* II: §25), motion is defined as the translation of a body from one neighbourhood of surrounding bodies into another. Descartes is careful to distinguish motion itself from its cause(s). While, as we have seen, motion is sometimes caused by the volition of a

mind, the general cause of motion in the inanimate world is God, who creates bodies and their motion, and sustains them from moment to moment. From the constancy of the way in which God sustains motion, Descartes argues, the same quantity of motion is always preserved in the world, a quantity that is measured by the size of a body multiplied by its speed (*Principles* II: §36). To this general conservation law he adds three more particular laws of nature, also based on the constancy by which God conserves his creation. According to the first law, everything retains its own state, in so far as it can. As a consequence, what is in motion remains in motion until interfered with by an external cause, a principle directly opposed to the Aristotelian view that things in motion tend to come to rest (*Principles* II: §§37-8). According to the second law, bodies tend to move in rectilinear paths, with the result that bodies in circular motion tend to move away at the tangent (*Principles* II: §39). The first and second laws together arguably constitute the first published statement of what Newton, later called the law of inertia. Descartes' third law governs the collision between bodies, specifying when one body imposes its motion on another, and when two bodies rebound from one another without exchanging motion. The abstract law is followed by seven specific rules covering special cases (*Principles* II: §§40-52). Though the law of collision turns out to be radically inadequate, it casts considerable light on Descartes' conception of the physical world. One of the determinants of the outcome of a collision is what Descartes calls the 'force' of a body, both its force for continuing in motion, and its resistance to change in its motion (*Principles* II: §43). The role of such forces in Descartes' mechanist world has generated much discussion, since they would seem to be completely inconsistent with Descartes' view that the essence of body is extension alone.

These general accounts of matter and motion form the basis of Descartes' physical theories of particular phenomena. The *Principles* goes on to explain how the earth turns around the sun in an enormous fluid vortex and how the light that comes from the sun is nothing but the centrifugal force of the fluid in the vortex, with ingenious explanations of many other particular phenomena in terms of the size, shape and motion of their parts. Other works contain further mechanistic explanations, for example of the law governing the refraction of light (*Dioptrics* II) and the way colours arise in the rainbow (*Meteors* VIII).

Descartes' hope was that he could begin with an assumption about how God created the world, and then deduce, on the basis of the laws of motion, how the world would have to have come out (*Discourse* V, VI; *Principles* III: §46). But this procedure caused some problems. It is not easy to specify just how God might have created the world - whether the particles that he first created were of the same size, for example, or of every possible size. Furthermore, any hypothesis of this sort would seem to be inconsistent with the account of creation in Genesis (*Principles* III: §§43-7). These difficulties aside, it seemed obvious to Descartes how to proceed. For example, from his denial of the vacuum it would seem to follow that bodies in motion would sort themselves out into circular swirls of matter, the vortices which were to explain the circulation of the planets around a central sun. Similarly, Descartes used the tendency to centrifugal motion generated by the circular motion of the vortex to explain light, which, he claimed, was the pressure of the subtle matter in the vortex. But the very complexity of the world militates against the full certainty that Descartes originally sought, particularly when dealing with the explanation of particular phenomena, such as the magnet. Indeed, by the end of the *Principles*, it can seem that he has given up the goal of certainty and come to accept the kind of probability that he initially rejected (*Principles* IV:§204-6).

Central to Descartes' physics is his rejection of final causes: 'When dealing with natural things we will, then, never derive any explanations from the purposes which God or nature may have had in view when creating them. For we should not be so arrogant as to suppose that we can share in God's plans' (*Principles* I: §28). The emphasis on efficient causes was to prove very controversial later in the century.

One especially curious feature of Descartes' physics, however, is the lack of any substantive role for mathematics. Descartes was one of the great mathematicians of his age. While it is, perhaps, anachronistic to see modern analytic geometry and so-called Cartesian coordinates in his *Geometry* (1637), there is no question but that it is a work of real depth and influence. In it he shows how one could use algebra to solve geometric problems and geometry to solve algebraic problems by showing how algebraic operations could be interpreted purely in terms of the manipulation and construction of line segments. In traditional mathematics, if a quantity was represented as a given line, then the square of that quantity was represented as a square constructed with that line as a side, and the cube of the quantity represented as a cube constructed with that line as an edge, effectively limiting the geometric representation of algebraic operations to a very few. By demonstrating how the square, cube (and so on) of a given

quantity could all be represented as other lines, Descartes opened the way to a more complete unification of algebra and geometry. Also important to his mathematical work was the notion of analysis. Descartes saw himself as reviving the work of the ancient mathematician, Pappus of Alexandria, and setting out a methodology for the solution of problems, a methodology radically different from the Euclidean style of doing geometry in terms of definitions, axioms, postulates and propositions, which he regarded as a method of presentation rather than a method of discovery. According to the procedure of analysis, as Descartes understood it, one begins by labelling unknowns in a geometric problem with letters, setting out a series of equations that involve these letters, and then solving for the unknowns to the extent that this is possible.

Unlike his contemporary, Galileo, or his successors, Leibniz and Newton, Descartes never quite figured out how to apply his mathematical insights to the physical world. Indeed, it is a curious feature of his tree of knowledge that, despite the central place occupied by mathematics in his own accomplishments, it seems to have no place there.

12 Life and the foundations of biology

The last part of the Cartesian programme was his biology. First presented in the *Treatise on Man*, part of *The World* project which was abandoned in 1633 when Galileo was condemned, Descartes intended to rework some of that material and publish it - as Parts V and VI of the *Principles* under the title ‘De Homine’. Although he never finished this rewriting, it is clear from the notes left behind that it was very much on his mind in years that preceded his sudden and premature death.

His hope seems to have been to show how, from matter and the laws of motion alone, life would arise spontaneously as matter came to organize itself in an appropriate way (*Discourse* V). Unfortunately he never worked out this view, suggestive of later theories of evolution, in any detail. Yet, he was quite clear that all the functions of life (with the exception of thought and reason in humans) are to be explained not in terms of the soul, the principle of life, but in terms of matter in motion. Accordingly, in the *Treatise on Man*, he accounts for a variety of phenomena, including digestion, involuntary motion, the action of the heart, and sense perception, in purely mechanical terms. (Summarized in *Discourse* Part V, with special emphasis on the circulation of the blood.)

While Descartes’ biology was controversial among his contemporaries, one aspect was especially so. According to his account, there is only one kind of soul in the world, the rational soul, which humans and angels have and animals do not. Humans are organic machines, collections of matter organized so as to be able to perform vital functions, attached to rational souls. Animals, on the other hand, are just machines: their behaviour is purely mechanical and they are, strictly speaking, incapable of conscious experience of any sort (*Discourse* V).

13 The Cartesian heritage

It is difficult to overestimate the influence of Descartes. In philosophy, the Cogito Argument signalled the centrality of the self and the rejection of authority from without, the authority of both texts and teacher. For physics, Descartes represented the rejection of the scholastic physics of matter and form, and its replacement by a mechanistic physics of matter and motion. So in biology, he stood for mechanism and the rejection of Aristotelian vitalism.

Descartes had many followers who took his ideas (as they understood them) as dogma, and developed them as they thought he would have wanted them to do. The most important centres of Cartesian thought were France, where he was remembered as a countryman, despite his long absence, and the Netherlands, where he had lived. In France, his thought was carried on by a circle around Claude Clerselier, who gathered and published his letters as well as other works. Louis de La Forge commented on Descartes’ physiology, and wrote a Cartesian treatise on the mind, extending Descartes’ ideas. Gerauld de Cordemoy, tried to blend Cartesian philosophy with atomism, to the puzzlement of most of his contemporaries. Jacques Rohault was influential in Cartesian physics well after Newton had published the work that would eventually eclipse such theories. Other followers, mainly in the Low Countries, include Henricus Regius, considered Cartesian by many despite Descartes’ public rejection; Adriaan Heereboord, one of Descartes’ partisans in Leiden; Johannes de Raey, one of those who attempted to reconcile Descartes with the true philosophy of Aristotle; and Johannes Clauberg, who recast Cartesianism into more scholastic garb. There were many more minor Cartesians of various nationalities. Late seventeenth-century Europe was flooded with

paraphrases of and commentaries on Descartes' writings.

Other more independent thinkers were strongly influenced by Descartes without explicitly being followers. The best-known such figure is probably Nicolas Malebranche. While his thought owes much to other influences, particularly to seventeenth-century Augustinianism, in his *Recherche de la vérité (Search after Truth)* (1674-5) he follows Descartes in offering a critique of the senses, rejecting the authority of tradition, and appealing to clear and distinct perceptions. Descartes was also an important influence on the Cambridge Platonist Henry More, who regarded Descartes' philosophy, in particular his distinction between mind and body, as support for his own attacks on materialism (see Cambridge Platonism). Spinoza, too, was influenced by Descartes. His first published book was a commentary on Descartes' *Principles*, and although he later moved well outside the Cartesian camp, Descartes' doctrines helped to structure his mature thought. Spinoza's metaphysical vocabulary (substance, attribute and mode) is borrowed from Descartes, as is the centrality of the attributes of thought and extension in his metaphysics.

While many of Descartes' partisans tried to remain orthodox, there is at least one doctrine characteristic of later Cartesianism that Descartes himself probably did not hold, namely, occasionalism (see Occasionalism). Malebranche and the Flemish Cartesian Arnold Geulincx are most often associated with the doctrine, but it appears in Cartesian writings long before theirs. According to occasionalism, God is the only active causal agent in the world; finite minds and bodies are not real causes, but only occasions for God to exercise his causal efficacy. Motivated by the picture of divine sustenance from moment to moment that underlies Descartes' derivation of the laws of motion, together, perhaps, with general worries about the efficacy of finite causes and specific worries about mind - body interaction, occasionalism became a standard doctrine. Though often also attributed to Descartes himself, the grounds for doing so are rather slim.

Descartes' mark can also be seen among his opponents. He was clearly a target of Hobbes' materialism and sensationalism in, for example, Part I of *Leviathan* (1651). His epistemology and treatment of God were explicitly targeted by Pascal in the *Pensées* (1658-62, published 1670). Leibniz, too, attacked his physics, his rejection of formal logic, his conception of body and his conception of the mind, among many other things. The inadequacy of the Cartesian philosophy is a constant subtext to Locke's *Essay Concerning Human Understanding* (1689), particularly in his discussion of our knowledge of mind and his rejection of the dogmatic claim to know the essences of substances. In natural philosophy, Newton's early writings show a careful study of Descartes' writings, particularly those on motion, and book II of his *Principia* was devoted to a refutation of the vortex theory of planetary motion. Between around 1650 and the eclipse of Cartesian philosophy some time in the early eighteenth century, it was simply impossible to write philosophy without reacting in some way to Descartes.

DANIEL GARBER

List of works

Descartes, R. (1964-74) *Oeuvres de Descartes*, ed. C. Adam and P. Tannery, Paris: CNRS/Vrin, new edn, 11 vols. (Originally published 1897-1913, and more recently updated, this is still the standard edition of Descartes' writings in the original languages. It contains editions of all of the writings listed below, as well as his letters. The incomplete *La description du corps humain* and *Prima cogitationes* are included in volume 11.)

Descartes, R. (1984-91) *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 3 vols.(The now-standard English translation of Descartes' writings. It contains the entire *Rules*, *Discourse*, *Meditations* and *Passions*, as well as selections from his other writings and letters.)

Descartes, R. (1620-*c*.28) *Regulae ad directionem ingenii (Rules for the Direction of the Mind)*, in vol. 1 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91.(Descartes' early treatise on method, left unpublished at his death. Manuscripts were widely circulated, and it was published first in Dutch translation in 1684 and in the Latin original in 1701.)

Descartes, R. (c.1630-3) *Le Monde (The World)*, excerpted in vol. 1 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91.(Descartes' first draft of a scientific system, including general physics, cosmology, terrestrial

physics, and human physiology. Withdrawn from publication when Galileo was condemned, the *Treatise on Man* was first published in Latin translation in 1662, then in the French original in 1664; the *Treatise on Light* was first published in French in 1664.)

Descartes, R. (1637) *Discours de la méthode pour bien conduir sa raison et chercher la vérité dans les sciences plus la dioptrique, les meteores, et la geometrie, qui sont des essais de cete methode (Discourse on the Method for Properly Conducting Reason and Searching for Truth in the Sciences, as well as the Dioptrics, the Meteors, and the Geometry, which are essays in this method)*, in vol. 1 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91.(Descartes' first publication: three scientific treatises, together with an introduction that was to become more famous and widely read than the essays that it introduced.)

Descartes, R. (1641) *Meditationes de prima philosophia (Meditations on First Philosophy)*, in vol. 2 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91.(Descartes' main metaphysical work, it was published with a series of objections together with Descartes' replies, six sets in the 1641 edition; a seventh was added in the 1642 edition. Also important is the 1647 French translation, published with some changes.)

Descartes, R. (1644) *Principia philosophiae (Principles of Philosophy)*, excerpted in vol. 1 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91. (After Part I, which deals with metaphysics, this mainly deals with Descartes' physics. Also important is the 1647 French translation, with a new preface and some significant changes.)

Descartes, R. (1649) *Les passions de l'âme (The Passions of the Soul)*, in vol. 1 of *The Philosophical Writings of Descartes*, ed. and trans. J. Cottingham, R. Stoothoff, D. Murdoch and A. Kenny, Cambridge: Cambridge University Press, 1984-91. (Descartes' last published work, this deals with philosophical psychology and morals.)

References and further reading

The journal *Archives de Philosophie* annually publishes a report from the Centre d'études cartésiennes (Université de Paris IV (Sorbonne)), which contains full bibliographies of recent work on Descartes and Cartesianism, together with selective reviews.

Baillet, A. (1691) *La Vie de M. Descartes (Life of Descartes)*, Paris: Daniel Horthemels, 2 vols.(The most important source on Descartes' life. It was his 'official' biography, commissioned by a circle of Descartes' followers. Baillet had access to numerous papers that are no longer extant.)

Williams, B. (1978) *Descartes: the Project of Pure Enquiry*, Hassock: Harvester. (Classic introduction to Descartes' philosophical thought from an analytic point of view.)

Wilson, M. (1978) *Descartes*, London: Routledge.(An excellent and influential commentary, centred on the *Meditations*.)

Descriptions

'Definite descriptions' are noun phrases of the form 'the' + noun complex (for example, 'the finest Greek poet', 'the cube of five') or of the form possessive + noun complex (for example, 'Sparta's defeat of Athens'). As Russell realized, it is important to philosophy to be clear about the semantics of such expressions. In the sentence 'Aeschylus fought at Marathon', the function of the subject, 'Aeschylus', is to refer to something; it is a referential noun phrase (or 'singular term'). By contrast, in the sentence 'Every Athenian remembers Marathon', the subject noun phrase, 'every Athenian', is not referential but quantificational. Definite descriptions appear at first sight to be referential. Frege treated them referentially, but Russell held that they should be treated quantificationally in accordance with his theory of descriptions, and argued that certain philosophical puzzles were thereby solved.

1 Frege

Gottlob Frege provided the first systematic account of quantification in natural language and the first systematic theory of reference (1892). The class of 'singular terms' (referential noun phrases), for Frege, was delimited by a set of logical tests (for example, the licensing of existential generalization) and was recursive. It included ordinary proper names and definite descriptions. Thus '5', 'the cube of 5', 'Aeschylus' and so on were all singular terms.

If a description $\ulcorner \text{the } F \urcorner$ is referential, then it is natural to take its reference to be the unique entity satisfying '*F*'; a sentence $\ulcorner \text{The } F \text{ is } G \urcorner$ is true if and only if that entity is *G*. But what if no entity, or more than one entity, satisfies the descriptive condition, as in (1) or (2)?

(1) *The largest prime number* lies between 10^{23} and 10^{27}.
(2) *The man who landed on the moon* was American.

Such descriptions are said to be 'improper'. Frege considered it a defect of natural language that it permits the possibility of improper terms. As far as his own logical system was concerned, he thought it essential that every formula have a truth-value, and so he insisted that every singular term have a reference (or meaning): he stipulated that a specified object in the range of the quantifier(s) serve as the referent of every improper description. While this stipulation proved useful for his formal system, Frege recognized that some other account of improper descriptions in ordinary language was needed. Once he had made his distinction between the 'sense' and 'reference' of an expression, he suggested that an improper term has a sense but no reference (see Frege, G. §3; Sense and reference §1). The main problem with this proposal is that it predicts, rather counterintuitively, that any sentence containing an improper term (in a transparent context) lacks a truth-value. For example, it predicts that (1) and (2) above lack truth-values.

2 Russell's theory of descriptions: informal characterization

Like Frege, Bertrand Russell thought it important to explain how a sentence such as (1) or (2) could be meaningful. At one time he entertained the idea of a realm of non-existent entities to serve as the referents of descriptions such as 'the largest prime number' and 'the round square'; but by 1905 he thought this idea conflicted with a 'robust sense of reality' and his theory of descriptions came about, in part as an attempt to purify his ontology (see Existence §2).

On Russell's account, descriptions are not singular terms at all but phrases that logical analysis reveals to be quantificational: if $\ulcorner \text{the } F \urcorner$ is a definite description and $\ulcorner \ldots \text{is } G \urcorner$ is a predicate phrase, then the proposition expressed by an utterance of $\ulcorner \text{The } F \text{ is } G \urcorner$ is equivalent, says Russell, to the proposition expressed by an utterance of $\ulcorner$There is exactly one *F*, and everything that is *F* is $G \urcorner$. That is, $\ulcorner$The *F* is $G \urcorner$ is analysed as

(3) $(\exists x)((\forall y)(Fy \leftrightarrow y = x) \;\&\; Gx)$.

The proposition expressed by $\ulcorner \text{The } F \text{ is } G \urcorner$ is 'general' ('object-independent') rather than 'singular' ('object-dependent') in the sense that there is no object for which its grammatical subject stands; upon whose existence that of the proposition expressed depends. Unlike a singular term, a definite description, even if it is in fact satisfied by a unique object, does not actually *refer* to that object. It is as wrong, on Russell's account, to inquire into the referent of $\ulcorner \text{the } F \urcorner$ as it is to inquire into the referent of $\ulcorner \text{every } F \urcorner$ or $\ulcorner \text{no } F \urcorner$.

On Russell's account, sentences containing improper descriptions have truth-values. For example, (1) above is false as it is not the case that there exists a largest prime number. Similarly, sentence (2) is false as it is not the case that there exists exactly one man who landed on the moon.

Russell's theory opens up the possibility of accounting for certain *de dicto*/*de re* ambiguities in terms of scope permutations (see De re/de dicto). For example, (4) below may be analysed as either (5) or (6), according to whether the description 'the largest prime number' is given large or small scope with respect to 'John thinks that':

(4) John thinks that the largest prime number lies between 10^{23} and 10^{27}.
(5) $(\exists x)((\forall y)(\text{largest-prime } y \leftrightarrow y = x)$ & John thinks that: *x* lies between 10^{23} and 10^{27}).
(6) John thinks that: $(\exists x)((\forall y)(\text{largest-prime } y \leftrightarrow y = x)$ & *x* lies between 10^{23} and 10^{27}).

(5) is false; but (6) may be true. Thus Russell is able to explain the intuitive ambiguity of (4) and avoid positing an ontology that includes such things as a largest prime number. Smullyan (1948) points out that Russell's theory similarly explains *de dicto*/*de re* ambiguities in modal contexts, for example, in 'The number of planets is necessarily odd' (see De re/de dicto §2; Modal logic).

Russell came to treat ordinary proper names as 'disguised' or 'truncated' descriptions. For example, the name 'Cicero' might be analysed as the description 'the greatest Roman orator' while the coreferential name 'Tully' might be analysed as the description 'the author of *De Fato*'. On the face of it, this provided Russell with accounts (not dissimilar to Frege's) of why 'Cicero was bald' and 'Tully was bald' differ in informativeness, and of why (7) and (8) need not agree in truth-value:

(7) John believes Cicero was bald.
(8) John believes Tully was bald.

In the light of Kripke's work on names and necessity (1980), it is widely held that descriptive analyses of proper names cannot succeed (see Proper names). There is good reason, however, to think that at least some pronouns anaphorically linked to (referring back to), but not bound by, quantified noun phrases are understood in terms of definite descriptions (see Neale 1990).

3 Russell's theory of descriptions: formal characterization

On Russell's account, descriptions are 'incomplete' symbols; they have 'no meaning in isolation', that is, they do not stand for things. In *Principia Mathematica* (1910-13), descriptions are represented by quasi-singular terms of the form '$(\iota x)(Fx)$', which can be read as 'the unique *x* which is *F*'. Superficially, the iota-operator is a variable-binding device for forming a term from a formula. A predicate symbol '*G*' may be prefixed to a description '$(\iota x)(Fx)$' to form a formula '$G(\iota x)(Fx)$', which can be expanded in accordance with a suitable 'contextual definition'. (To define an expression ζ contextually is to provide a procedure for converting any sentence containing occurrences of ζ into an equivalent sentence that is ζ-free.)

The analysis in (3) above does not constitute a final contextual definition of '$G(\iota x)(Fx)$' because of the possibility of scope ambiguity where a formula containing a description is itself a constituent of a larger formula (see Scope). Scope ambiguity is conveniently illustrated with descriptions in the context of negation. For a genuine singular term α, there is no difference between wide and narrow scope negation: α is not-*F* just in case it is not the case that α is *F*. For a description, however, there is a formal ambiguity. Let '*Kx*' represent '*x* is a king of France' and '*Wx*' represent '*x* is wise'. Then the formula '$\neg W(\iota x)(Kx)$' ('The king of France is not wise') is ambiguous between (9) and (10):

(9) $(\exists x)((\forall y)(Ky \leftrightarrow y = x)$ & $\neg Wx)$
(10) $\neg(\exists x)((\forall y)(Ky \leftrightarrow y = x)$ & $Wx)$.

These are not equivalent: only (10) can be true when there is no king of France. In *Principia Mathematica*, the scope of a description is specified by appending a copy of it within square brackets to the front of the formula that constitutes its scope. Thus (9) and (10) are represented as (11) and (12) respectively:

(11) $[(\iota x)(Kx)]\neg\{W(\iota x)(Kx)\}$
(12) $\neg\{[(\iota x)(Kx)]W(\iota x)(Kx)\}$.

In (11) the description has what Russell calls a ‘primary occurrence’ by virtue of having scope over the negation; in (12) the description has a ‘secondary occurrence’ by virtue of lying within the scope of the negation. Where a description has smallest possible scope, it is conventional to omit the scope marker; thus (12) can be reduced to ‘ $\neg W(\iota x)(Kx)$’.

With the matter of scope behind us, the theory of descriptions can be stated exactly:

$[(\iota x)(\phi x)]G(\iota x)(\phi x) =_{\mathrm{df}} (\exists x)((\forall y)(\phi y \leftrightarrow y = x) \;\&\; Gx),$

where ϕ is a formula. On Russell’s account, there is no possibility of a genuine referring expression failing to refer, so no predicate letter in the language of *Principia Mathematica* stands for ‘exists’. Russell introduces a symbol ‘E!’ (‘E shriek’) that may be combined with a description to create a well-formed formula. Thus

$\mathrm{E!}(\iota x)(\phi x) =_{\mathrm{df}} (\exists x)(\forall y)(\phi y \leftrightarrow y = x).$

‘E!’ allows a treatment of negative existentials. (According to Russell, an utterance of ‘The king of France does not exist’ made today would be true precisely because there is no king of France.) Successive applications will allow any well-formed formula containing a definite description to be replaced by an equivalent formula that is description-free.

It is often objected that Russell’s theory, which substitutes complex quantificational structure for ‘the’, is unfaithful to surface syntax. The objection is engendered by an insufficiently keen appreciation of the distinction between a theory and its formal implementation. The extent of the mismatch between ‘The king is wise’ and its analysis

(13) $(\exists x)((\forall y)(\text{king } y \leftrightarrow y = x) \;\&\; \text{wise } x)$

has nothing to do with descriptions *per se*. In order to characterize the logical forms of even ‘some philosophers are wise’ and ‘every philosopher is wise’ in the predicate calculus we have to use formulas containing sentence connectives, no counterparts of which occur in the surface forms of the sentences:

(14) $(\exists x)$(philosopher *x* & wise *x*)
(15) $(\forall x)$(philosopher $x \rightarrow$ wise *x*).

And when we formalize sentences such as ‘Just two philosophers are wise’, we find much more complexity than there is in surface syntax:

(16) $(\exists x)(\exists y)$[philosopher *x* & philosopher *y* & wise *x* & wise *y* & $(\forall z)$((philosopher *z* & wise *z*) $\rightarrow z = x \vee z = y$)].

The supposed problem about descriptions, then, is in fact a symptom of a larger problem involving the application of first-order logic to sentences of ordinary language.

Work on ‘generalized’ quantification provides a solution to the larger problem (as well as treatments of quantifiers such as ‘most’ that cannot be handled within first-order logic; see Quantifiers, generalized). Natural language quantification is normally restricted: we talk about all philosophers or most poets, not about all or most entities. A simple modification of the predicate calculus yields a language - call it ‘RQ’ - that captures this fact while retaining the precision of regular first-order logic. In RQ, a determiner such as ‘some’, ‘every’ or ‘no’ combines with a formula to create a restricted quantifier such as ‘[every *x*: philosopher *x*]’. And such a quantifier may combine with a formula to form a formula:

(17) [every *x*: philosopher *x*] (wise *x*).

The viability of such a language shows that the language of *Principia Mathematica* is not essential to the theory of descriptions. Since the word ‘the’ is a one-place quantificational determiner (as are ‘some’, ‘every’, ‘no’ and so on), RQ can treat ‘the’ as combining with a formula ‘king *x*’ to form a restricted quantifier ‘[the *x*: king *x*]’. The sentence ‘The king is wise’ will then be represented as

(18) [the *x*: king *x*] (wise *x*).

Different scope possibilities are easily captured. For instance, ‘The king is not wise’ is ambiguous between (19) and (20):

(19) [the *x*: king *x*] ¬(wise *x*)
(20) ¬[the *x*: king *x*](wise *x*).

Using a formal language in which descriptions are treated as restricted quantifiers does not mean abandoning Russell’s view that descriptions are ‘incomplete symbols’ that ‘disappear on analysis’. Rather, treating descriptions as restricted quantifiers results in an explanation of where his theory of descriptions fits into a systematic account of natural language quantification, a theory in which ‘every’, ‘some’, ‘most’, ‘a’, ‘the’ and so on are members of a unified syntactic and semantic category.

4 Strawson’s theory and criticisms of Russell

As part of a broad critique of the idea that the semantics of formal languages can be used to analyse the meanings of statements of natural language, P.F. Strawson argued against Russell’s theory of descriptions on the grounds that (1) it fails to recognize that referring is something done by speakers and not expressions, (2) it fails to do justice to the way speakers ordinarily use sentences containing descriptions to make statements (speakers use descriptions to refer, not to quantify) and (3) it rides roughshod over important distinctions, such as the distinction between the meaning of a sentence σ and the statement made by a particular use of σ (see Propositions, sentences and statements).

Using as an example ‘The present king of France is wise’, Strawson argues that Russell’s theory is thwarted because the same sentence can be used to say something true on one occasion and something false on another. It is certainly true that Russell paid little attention to the distinction between the linguistic meaning of a sentence type and the proposition expressed by a particular dated utterance of that sentence type; but it was the latter that actually concerned him, and Strawson could get no mileage out of Russell’s inattention to the distinction. The fact that a description (or any other quantified noun phrase) may contain an indexical component (‘the *present* king of France’, ‘every man *here*’, and so on) illustrates that some descriptions are subject to both the theory of descriptions and a theory of indexicality (see Demonstratives and indexicals). Thus contextual features play a role in fixing the proposition expressed. And this can be true also if the overt indexical element is missing, as in ‘The king of France is wise’.

This appreciation of contextual factors forms the basis of the Russellian response to a second Strawsonian objection. According to this, someone who uses a description $\ulcorner \mathrm{the}\ F \urcorner$ typically intends to refer to some object or other and say something about it; there is no question of claiming that some object uniquely satisfies *F*. Someone who says ‘The table is covered with books’, for instance, does not express a proposition that entails the existence of exactly one table. But, Strawson claimed, it is a part of the meaning of $\ulcorner \mathrm{the}\ F \urcorner$ that such an expression is used correctly only if there is an *F*. If this condition is not satisfied - if the ‘presupposition’ that there is an *F* is false - a use of $\ulcorner \mathrm{The}\ F\ \mathrm{is}\ G \urcorner$ cannot be considered to express a proposition that is either true or false. The Russellian response to Strawson is that descriptions such as ‘the table’ are often understood as elliptical uses of fuller descriptions such as ‘the table over there’, ‘the table in front of me’ and so on; or else they are evaluated with respect to a restricted domain of discourse. Again the phenomenon is not confined to descriptions, but is found with quantified noun phrases more generally.

Strawson’s original statement (1950) of his own theory contains an interesting ambiguity. He can be understood as claiming either that no proposition is expressed, or that a proposition which is neither true nor false is expressed, when someone uses a sentence containing an empty description. A second ambiguity comes with the notion of ‘presupposition’. This can be viewed as an epistemological or pragmatic relation between a person and a statement, or as a logical relation between two statements (see Presupposition). An epistemological or pragmatic notion of presupposition appears to have no bearing on the semantic issues Strawson wanted to address when he challenged Russell.

The Strawsonian position faces some serious obstacles. If someone were to utter (21) right now, they would unquestionably say something false.

(21) The king of France shot my cat last night.

But on Strawson's account, the speaker will have expressed no proposition because the presupposition that there is a unique king of France is false. Descriptions occurring in the context of attitude verbs create a similar problem. For example, someone might utter a true statement using (22):

(22) Ponce de León thought the fountain of youth was in Florida,

so the presence of an empty description does not always result in a failed speech act. This is something Strawson (1964) came to concede. In order to reduce the number of incorrect predictions made by his earlier theory, he suggested that the presence of an empty description sometimes renders the proposition expressed false and at other times prevents a proposition from being expressed at all (sometimes $\ulcorner$The F is $G\urcorner$ *entails* the existence of a unique *F*, and at other times it (only) *presupposes* it).

5 Ambiguity theories

Consideration of the behaviour of descriptions in non-extensional contexts and the possibility of misdescribing an individual as the *F*, but successfully communicating something about that individual, has led some philosophers (for example, Donnellan 1966) to suggest that descriptions are sometimes quantificational, at other times referential. When $\ulcorner$the $F\urcorner$ is used in the Russellian way, the proposition expressed is general (object-independent); when it is used referentially the proposition expressed is singular (object-dependent). Donnellan considers examples such as the following: (1) A detective discovers Smith's mutilated body but has no idea who killed him. Looking at the body, he exclaims, 'The murderer is insane'. (2) Jones is on trial for Smith's murder; I am convinced of his guilt; hearing Jones ranting in court, I say, 'The murderer is insane'. On Donnellan's account, in case (1) the description is being used attributively; in case (2) it is being used referentially. Cases such as (2), it is argued, cannot be treated in accordance with Russell's theory. Following Grice (1969), however, many have argued (1) that so-called referential uses of descriptions can usually be accommodated within Russell's theory by invoking a distinction between the proposition expressed by (an utterance of) a sentence on a given occasion and the proposition the speaker primarily intends to communicate on that occasion; (2) that the phenomenon of referential usage is not specific to definite descriptions, but arises with quantified noun phrases quite generally; (3) that the referential/attributive distinction is neither exclusive nor exhaustive; and (4) that no such distinction can do the work of Russell's notion of the scope of a description. It would seem, then, that something very close to Russell's theory will probably form a component of any finally acceptable theory.

Desert and merit

The ideas of desert and merit are fundamental to the way we normally think about our personal relationships and our social institutions. We believe that people who perform good deeds and display admirable qualities deserve praise, honours and rewards, whereas people whose behaviour is anti-social deserve blame and punishment. We also think that justice is in large part a matter of people receiving the treatment that they deserve. But many philosophers have found these ways of thinking hard to justify. Why should people's past deeds determine how we should treat them in the future? Since we cannot see inside their heads, how can we ever know what people really deserve? How can we reconcile our belief that people must be responsible for their actions in order to deserve credit or blame with the determinist claim that all actions are in principle capable of being explained by causes over which we have no control?

1 Desert and merit

We use the concepts of desert and merit when we are thinking about how it is appropriate to treat people in a wide range of contexts. We say that Einstein deserved the Nobel prize for his work in theoretical physics, that Nixon deserved to be impeached for his role in the Watergate cover-up, that Jane deserves more thanks from her children than she is getting, that nurses deserve to have their pay increased. All of these claims have essentially the same structure (see Feinberg 1970): there is a subject, either an individual like Einstein or a set of people like the nurses, who are said to be deserving; there is a characteristic or an activity in virtue of which they are said to be deserving, which I shall call the *desert base* - Einstein's researches, or the work that nurses do; and there is something that is deserved, a burden or a benefit that it is appropriate or fitting for the subject to have on account of the desert base - the Nobel prize, a pay award (see Praise and blame).

Both the treatment deserved and the desert base vary a great deal from case to case, and mistakes in analysing the concept of desert often arise from considering only one kind of example. We can say in general that the characteristic or activity that forms the desert base must be something that we value positively or, in the case of deserved blame or punishment, negatively (see Values). But the valuing can be of many different kinds. Sometimes people are said to deserve rewards for activities that are morally valuable - we might say, for instance, that the charitable work done by a great philanthropist deserves to be honoured. In other cases - such as those of athletes or scientists who are awarded prizes - we value someone's accomplishments without giving them moral credit. To suppose that all desert must be moral desert is to shrink the range of possible desert bases unwarrantably.

The concepts of desert and merit are linked closely, and some languages have only a single word where English has two. The main difference is that we tend to use desert when talking about someone's performance, and merit when talking about their personal capacities and abilities (see Lucas 1980). Thus when we say that appointments should be made on the basis of merit, we mean that the candidate who shows the greatest capacity to fill the position should be awarded it. On the other hand, when somebody has performed a courageous act or written an excellent essay, we usually say that they deserve something in return, a decoration or a grade. Desert also conveys the sense that the subject is responsible for what he does, whereas in pre-modern systems of thought, including that of ancient Greece, people were judged meritorious according to the quality of their actions, and with little regard to individual responsibility as we understand it (see Adkins 1960).

2 Desert and personal responsibility

What are the implications of saying that people deserve rewards, punishments and other modes of treatment only when they are responsible for the performance that forms the basis of desert (see Responsibility)? It means first of all that they must have intended to do what they did. If I gun down a desperado thinking that he is the sheriff, I do not deserve the price that has been put on his head. Moreover my deserts are lessened or even removed entirely to the extent that my performance depends on luck. I may win a competition through a lucky series of guesses, but the person who really deserved to win was the person who knew the answers all along. This link between desert and responsibility is particularly tight when punishment is at stake (see Crime and punishment). When legal systems punish people for occurrences they could have done nothing to prevent, we regard these punishments as undeserved and unfair. The driver who runs over a child even though he was taking good care and could have done

nothing to avoid the accident does not deserve blame or punishment, but sympathy.

Problems arise, however, when we reflect that people’s performances depend in nearly every case not only on their intentions and efforts but on circumstances beyond their control, including the natural talents that they bring to the performance. Einstein’s achievement in developing the theory of relativity required considerable innate mathematical ability as well as a stimulating early education in science. Many philosophers have concluded that genuine desert must be based only on those parts of people’s actions or characteristics for which they are responsible, for instance the efforts they make or the talents they have chosen to develop. Whatever stems from natural causes beyond their control is irrelevant.

But this conclusion, too, faces difficulties. For willingness to make an effort, or a decision to develop a talent, is likely to be affected by initial circumstances and natural abilities. Would Einstein have decided to work on the theory of relativity if he had not known that he had a talent for theoretical physics? As John Rawls puts it, the character that enables someone to make an effort ‘depends in large part upon fortunate family and social circumstances for which he can claim no credit’ (1971: 104).

It seems, then, that the notion of desert collapses if we insist that a deserving person must be personally responsible for all of the conditions necessary for their performance. To keep the link between desert and personal responsibility we must substitute a weaker understanding of responsibility, such that a person can be responsible for a performance even though that performance depends upon circumstances and capacities for which they were not responsible. So long as they intended to perform the activity, and were sufficiently in control of it (it wasn’t a lucky accident), they may deserve benefits on account of it, even though their performance depended on natural capacities that others might lack (see Moral luck).

3 Critics of desert

An alternative response is to insist that desert requires responsibility in the stronger sense, and then to say that, because no one is ever fully responsible in this sense for what they do, the concept of desert as ordinarily understood should be scrapped. This is often thought to follow from determinism (see Free will §1). If every human action and decision has ultimately a set of causes beyond the agent, the idea of desert must either be abandoned or be given a new meaning. Utilitarians have argued that to say of someone that they deserve something is only to say that it is socially useful to reward them for performing a certain service (see Utilitarianism).

The same conclusion - that desert is at best a secondary idea - has been arrived at in other ways too. As we have seen, desert as ordinarily understood very often looks to the past as a reason for assigning a benefit or burden now: criminals deserve punishment for their past misdeeds; Einstein deservedly won the Nobel prize in 1921 for work done fifteen years earlier. But this appears to collide with the principle that in deciding how to act, we should consider only the future effects of our actions, which many have taken to be a requirement of practical rationality. On this view, we must reinterpret desert in forward-looking terms - we must estimate people’s deserts by considering the consequences of different ways of allocating our resources, rather than looking back at what they have already done - if we are to have any good reason to give people what they deserve.

A third line of attack is to suggest that we cannot establish what people deserve until we know which institutions are fair. It is an illusion to suppose that people have deserts in advance of social institutions like competitions, honours systems, or property systems, which are conventional in nature (see Property). When we say that people deserve things, what we mean is that they are legitimately entitled to them; these are the benefits they would expect to get, or the burdens they would expect to suffer, if the institutions were fair and working as they should. Once again the effect is to relegate desert to the status of a secondary moral idea.

We can now see what is required in order to defend something like our ordinary concept of desert. First, we must either reject determinism, or else argue that determinism is compatible with personal responsibility in a sense strong enough to support desert. Second, we must defend what Sher (1987) has called ‘antecedentialism’, the view that an act or occurrence may be called for because it would stand in a certain relation to some antecedent act or event. Third, we must show that our judgments about desert are sufficiently independent of institutional conventions for desert to function as a critical standard which we can appeal to when deciding which institutions to adopt.

4 Desert and justice

Justice often requires us to give people what they deserve (see Justice). Where it does not, this is usually because it is beyond our power to bring about the deserved outcome, or because attempting to do so would have unjust side effects (we cannot ensure that the best athlete wins the race or that good people find the partners they deserve). But if a society allows women to be paid less than men for doing the same job, or punishes lesser crimes more severely than greater crimes, it is to that extent unjust, and we have an obligation to change it.

The assumptions underlying this claim have been challenged both by conservatives and by radicals, who converge in thinking that 'desert' and 'merit' are too subjective to stand as independent criteria of distribution. Hume argued that merit might seem the most natural basis of distribution but 'so great is the uncertainty of merit, both from its natural obscurity, and from the self-conceit of each individual, that no determinate rule of conduct would ever result from it' (1751: 193). More recently, Hayek (1960) has argued along similar lines (see Hume, D.; Hayek, F.A.). They both make two errors. One is to suppose that desert must mean moral desert; the difficulty of making objective estimates of moral deservingness does not imply that other measures of desert - such as economic productivity - are equally obscure. The other error is to suppose that desert must supplant all other forms of entitlement, rather than serving as a critical standard by which existing entitlements can be judged, and new ones created.

Radicals claim that standards of desert and merit are socially constructed to support existing practices and institutions (see Young 1990). We can see this claim deployed in debates over affirmative action. When it is argued that giving preference to women or racial minorities in the allocation of jobs or college places conflicts with the principle of merit, the critics reply that 'merit' here merely refers to qualities which existing (male, white) society has chosen to designate as relevant. This criticism is likely to backfire, however, because if merit is abandoned altogether, it appears to open the door to practices that discriminate more openly and directly against disadvantaged groups (see Discrimination).

Justice is more than the requital of desert. It sometimes demands rule-following and respect for existing entitlement, sometimes equal treatment, or distribution according to need (see Equality; Needs and interests). But to divorce justice and desert entirely would be to abandon some of our most deeply held convictions for reasons which may be less than compelling.

Desgabets, Robert (1610-78)

Although he is now little known, Desgabets was an important seventeenth-century French philosopher, theologian, scientist and mathematician. An early defender of Cartesian philosophy, his physical explication of transubstantiation created such an uproar that he complied with a public order and renounced his views. He defended the essential union and interaction of soul and body, and the free creation of the eternal truths. The latter view led him to an empiricist epistemology: all ideas have a sensory basis and are essentially related to existing objects. Despite his originality, he is best known for his polemic with Foucher.

Robert Desgabets, Benedictine monk and early defender of Cartesian philosophy, was born in Ancemont, France. He was active in the Cartesian circles of Paris and Toulouse, well known to Clerselier, Rohault, Malebranche, Cordemoy, Retz and Régis. Despite his busy ecclesiastical career, he was *au courant* with the latest scientific discoveries. His pioneering work on blood transfusion inspired the French physician Jean Denis to attempt the procedure for the first time on a human subject (the subject lived, but the procedure was not successful). During his lifetime, only three small works were published: *'Discourse de la communication ou transfusion du sang' (Discourse on the communication or transfusion of blood)* (1668), *Considérations sur l'état présent de la controverse touchant le Très Saint-Sacrement de l'autel (Considerations on the present state of the controversy concerning the Holy Sacrament)* (1671) and *Critique de la Critique de la Recherche de la vérité (Critique of the Critique of the Search After Truth)* (1675). However, many of his philosophical manuscripts are known to have circulated widely in Cartesian circles; Régis was greatly influenced by his ideas.

Desgabets' writings deal with a broad range of philosophical, scientific and theological issues. His *Traité de l'indéfectibilité des créatures (Treatise on the indefectibility of created beings)* (*c*.1654), contains 'the indefectibility thesis', his most original thesis, drawn from Descartes' doctrine that God is the free and indifferent cause of everything, including the eternal truths and essences. Desgabets reasoned that if everything was created by an immutable, indivisible act of God's will then substances were created in their essence as well as their existence. There is no priority of intelligible essence over material existence since both are equally contingent on the omnipotent will of God. Thus, every substance is equally indestructible, necessary and real in both its essence and existence. The epistemological upshot of favouring divine omnipotence over divine wisdom is empiricism, since if God's will is not constrained by rational considerations then any a priori basis for knowledge is upset, leaving experience as the only means for knowing what God actually created. Desgabets thus lays the metaphysical foundation for the Cartesian empiricism which he subsequently developed over twenty years.

His *Le guide de la raison naturelle (Guide to Natural Reason)* (1671) is an examination of the principles and limits of reason. On the assumption that substances are created, he argues that conceivability itself has its source in created substance. He concludes that to conceive of an object is to have an idea of an actually existing object. It is the essential intentionality of ideas which ensures that simple conceptions are always true.

His important *Supplément à la philosophie de M. Descartes (Supplement to the philosophy of Descartes)* (1675) is an examination of the basic principles of Cartesianism, with corrections of Descartes' alleged errors. In this work his empiricism is fully developed. From Descartes' doctrines of soul-body union and interaction, he derives the empiricist claims that all that is in the soul passes through the senses, that all thoughts are accompanied by sensible signs or words, and that our thoughts have succession and duration which are inseparable from bodily movement. Even the *Cogito* involves the succession of ideas, which itself presupposes the idea of extension or body. Thus, the mind is not better known than body. Nor is the first principle of philosophy the *Cogito*, but rather, that all simple conceptions are always true and conform to their objects.

In physics, Desgabets' fidelity to Descartes' ideas is readily evident. He praises Descartes' system of physics against that of Gassendi, arguing that the essence of matter is extension, that sensible qualities belong to mind, and that a void is impossible. Moreover, he rejects Cordemoy's atomist revision of Cartesianism as one based on a false conception of the continuum and infinite divisibility: if atoms have extension, then they have parts, and if they have parts then they are divisible.

Critique of the Critique of the Search After Truth is a polemical defence of Malebranche against the sceptic

Foucher. Desgabets challenges Foucher's 'most odious' doctrine that ideas must resemble their objects in order to represent them. Both Malebranche and Desgabets follow Descartes in the belief that resemblance is not necessary for representation. However, Desgabets opts for a different account to that of Malebranche, explicating the relation between ideas and their objects in terms of an 'essential and intentional relation' (see Malebranche, N. §3).

Desgabets did not believe that reason and faith are opposed, but thought that theological revelation should be made consistent with philosophy. In *Considerations on the present state of the controversy concerning the Holy Sacrament* he argues that the new philosophical reformation is a product of joining mathematics to philosophy, which has enabled the explication of theological mysteries such as that of the Eucharist. That matter and quantity are the same thing means that there cannot be quantity without substance. This entails that if the body of Christ is present in the Host then it is actually present, that is, locally extended. Not surprisingly, Desgabets' views were judged by fellow ecclesiastics - notably Arnauld - to be completely against tradition. After a public trial and retraction, which resulted in a future ban on his writings, he retreated from public life to a monastery at Breuil, France. Fortunately, under the protection of Cardinal de Retz, he produced some of his best philosophical writings and participated in Cartesian conferences at Commercy.

Desgabets' system is erected on two basic and connected theses: the free creation of the eternal truths and essences, and the principle that simple conceptions contain a demonstrative proof of the reality and existence of their objects. His significance lies in his development and defence of a form of empiricism that, despite its anti-rationalist tendencies, has a clear basis in the work of Descartes himself and constitutes a respectable strain of Cartesianism.

Determinism and indeterminism

Over the centuries, the doctrine of determinism has been understood, and assessed, in different ways. Since the seventeenth century, it has been commonly understood as the doctrine that every event has a cause; or as the predictability, in principle, of the entire future. To assess the truth of determinism, so understood, philosophers have often looked to physical science; they have assumed that their current best physical theory is their best guide to the truth of determinism. It seems that most have believed that classical physics, especially Newton's physics, is deterministic. And in this century, most have believed that quantum theory is indeterministic. Since quantum theory has superseded classical physics, philosophers have typically come to the tentative conclusion that determinism is false.

In fact, these impressions are badly misleading. The above formulations of determinism are unsatisfactory. Once we use a better formulation, we see that there is a large gap between the determinism of a given physical theory, and the bolder, vague idea that motivated the traditional formulations: the idea that the world in itself is deterministic. Admittedly, one can make sense of this idea by adopting a sufficiently bold metaphysics; but it cannot be made sense of just by considering determinism for physical theories.

As regards physical theories, the traditional impression is again misleading. Which theories are deterministic turns out to be a subtle and complicated matter, with many open questions. But broadly speaking, it turns out that much of classical physics, even much of Newton's physics, is indeterministic. Furthermore, the alleged indeterminism of quantum theory is very controversial: it enters, if at all, only in quantum theory's account of measurement processes, an account which remains the most controversial part of the theory.

1 Consensus

Over the centuries, the doctrine of determinism has been understood, and its truth or falsity assessed, in different ways. (We follow the nearly universal practice of taking 'indeterminism' as simply the negation of determinism; so our discussion can focus on determinism.) Since the rise of modern science in the seventeenth century, it has been commonly understood as the 'law of universal causation', that every event has a cause; or as the predictability, in principle, of all of the future, given full knowledge of the present.

What evidence a philosopher takes to count for or against this doctrine varies immensely from one philosopher to another, according to their philosophical project. For example, many assess determinism in the light of their opinions about such metaphysical topics as free will or God (see Free will; Omniscience §3). Others see connections between determinism and broadly logical topics about time (see Many-valued logics, philosophical issues in §1). But this entry is restricted to formulating determinism, and assessing whether it is true, by considering the deliverances of physical theory. Of course, this restriction does not mean that our discussion only applies to wholly secular philosophers: many theistic philosophers, for example Kant, have discussed determinism in terms of the physics of their day. Some have even endorsed it, as part of their philosophy of nature; again Kant provides the outstanding example (see Kant, I. §7).

Making this restriction, we can say that since the seventeenth century, philosophers have typically taken their current best physical theory as their guide to the truth of determinism. And during the second half of this period, there has been a remarkable consensus about what that best theory is, and what it indicates about determinism.

During the nineteenth century, most of the educated public took Newtonian mechanics, and especially the Newtonian theory of gravitation, to be their best physical theory. Indeed, many took it to be an unrevisable foundation for physical theorizing. At its simplest, the idea was that Newton had laid down in his mechanics a schema for the mechanical explanation of the physical world. The schema was encapsulated in Newton's second law, that the force on a body is equal to its mass times its acceleration. Knowing the force and the mass, one could calculate the acceleration, and thus how the body moved. So to get a mechanical explanation of a given phenomenon, one had only to 'fill in the schema' by finding the forces involved. The paradigm case was of course gravitation; here Newton himself had discovered the nature of the force, and had calculated with stunning success how the planets and other celestial bodies move. Accordingly, many believed that Newtonian mechanics could in principle describe any phenomenon, perhaps by postulating strange forces (see Mechanics, classical §2).

They also believed that all the theories that could arise by thus filling in the schema would be deterministic; for the motion of a body would be determined by the forces on it (together with its initial position and velocity). The *locus classicus* for this view is a passage by Laplace, in which he not only states the doctrine that Newtonian mechanics is deterministic, but also provides formulations of determinism - first, in terms of causation, and then in terms of prediction; we shall later have reason to criticize both the doctrine and the formulations.

> We ought then to regard the present state of the universe as the effect of its anterior state and as the cause of the one which is to follow. Given for one instant an intelligence which could comprehend all the forces by which nature is animated and the respective situation of the beings who compose it - an intelligence sufficiently vast to submit these data to analysis - it would embrace in the same formula the movements of the greatest bodies of the universe and those of the lightest atom; for it, nothing would be uncertain and the future, as the past, would be present to its eyes. The human mind offers, in the perfection which it has been able to give to astronomy, a feeble idea of such an intelligence.
>
> (Laplace [1820] 1951: 4)

During the twentieth century, quantum theory and relativity theory became our best physical theories; by 1930, they had superseded classical physics. Since these theories are comparatively new and technically demanding, they have not become part of 'educated common sense' in the way in which Newtonian theories did (at least eventually, say by the mid-nineteenth century). But most philosophers who have addressed the topic have concluded that while relativity theory is deterministic, quantum theory is indeterministic. Indeterminism is taken to be the lesson of the much-cited uncertainty principle. This conclusion also has authority on its side: the great majority of the discoverers of quantum theory endorse it. So philosophers have typically come to the tentative conclusion that determinism is false.

2 Controversy

But this consensus has been badly misleading. First of all, formulations of determinism in terms of causation or predictability are unsatisfactory. And once we use a correct formulation, it turns out that much of classical physics, even much Newtonian physics, is indeterministic; and that parts of relativity theory are indeterministic (owing to singularities). Furthermore, the alleged indeterminism of quantum theory is very controversial - for it enters only, if at all, in quantum theory's account of measurement processes, an account which remains the most controversial part of the theory.

Formulations of determinism in terms of causation or predictability are unsatisfactory, precisely because of philosophers' interest in assessing determinism by considering physical theories. That interest means that determinism should be formulated in terms that are clearly related to such theories. But 'event', 'causation' and 'prediction' are vague and controversial notions, and are not used (at least not univocally) in most physical theories. Prediction has the further defect of being an epistemological notion - hence Laplace's appeal to an 'intelligence'; while the intuitive idea of determinism concerns the ontology or 'world-picture' of a given theory (see Causation; Events).

Fortunately, the intuitive idea of determinism can be formulated quite precisely, without these notions. The key idea is that determinism is a property of a theory. Imagine a theory that ascribes properties to objects of a certain kind, and claims that the sequence through time of any such object's properties satisfies certain regularities. In physics, such objects are usually called 'systems'; the properties are called 'states'; and the regularities are called 'the laws of the theory'. Then we say that the theory is deterministic if and only if for any two such systems: if they are in exactly the same state as one another at a given time, then according to the theory (for example, its laws about the evolution of states over time), they will at all future times be in the same state as one another. (Montague 1974, pioneered this kind of formulation.)

We can make determinism even more precise in the context of specific physical theories, by using their notions of system, state and law (regularity). But the classification of theories as deterministic or indeterministic is not completely automatic. For the notions of system, and so on, are often not precise in a physical theory as usually formulated. So various different formulations of determinism are often in principle legitimate for a given theory; and there is room for judgment about which formulation is interpretatively best.

However, it is well-established that the main conclusions are as reported above. The philosopher who has done most to classify physical theories in this way is Earman (1986), who upholds these main conclusions. We shall just briefly support these conclusions with two points that his book does not cover. (The details of the above formulation of determinism will not be needed for these points.)

First, much Newtonian physics is indeterministic. Indeed, indeterminism is lurking in the paradigm case discussed by Laplace: point-masses influenced only by their mutual gravitational attraction, as described by Newton’s law of gravitation.

But surely the motion of each point-mass is determined by thus forces on it, in this setting the gravitational force (together with its initial position and velocity)? (See Mechanics, classical §2.) Indeed it is, *locally*. That is: given the initial positions, velocities and forces, the motion of each point-mass is determined, for *some* interval of time extending into the future. But it might be a very short interval. (Technically, the equations of the theory have a unique solution for some interval of time, perhaps a very short one.) Furthermore, as time goes on, the interval of time for which there is such a solution might get shorter, shrinking to zero, in such a way that after some period of time, the solution does not exist any more. In effect, determinism might hold locally in time, and yet break down globally.

One way this might happen is by collisions: in general, Newtonian mechanics is silent about what would happen after two or more point-masses collide. But more interestingly, it seems that it might also happen *without* collisions. Thus it was conjectured in 1897 that one might somehow arrange for one of the point-masses to accelerate in a given spatial direction, ever more rapidly and at so great a rate, during a period of time, in such a way that it does not exist in space at the end of the period! By that time, it has disappeared to ‘spatial infinity’. (The source for the energy needed by the acceleration is the infinite potential well-associated with Newton’s inverse-square law of gravitation.) That this can indeed happen with just Newtonian gravity was finally proved true by Xia in 1992 (using a system of five point-masses). So now we know that, even setting aside collisions, Laplace’s vision of Newtonian determinism is only valid for local intervals of time.

Second, quantum theory can be interpreted as being deterministic. De Broglie and Bohm showed that such an interpretation of elementary quantum theory is possible, despite the alleged proofs that it was impossible (given in the 1930s by some of the discoverers of quantum theory). The basic idea is that a quantum system consists of both a wave and a particle. The wave evolves deterministically over time according to the fundamental equation of quantum theory (the Schrödinger equation) and it determines the particle’s motion, which therefore also moves deterministically, given the wave (hence this interpretation is also called the pilot wave interpretation). This contrasts with the orthodox interpretation. Roughly speaking, the orthodox interpretation accepts only the wave, and accommodates particle-like phenomena by having the wave evolve indeterministically (violating the Schrödinger equation) during processes of measurement (see Quantum mechanics, interpretation of §3; Quantum measurement problem). In recent years, the de Broglie-Bohm approach has been greatly developed so as to yield a deterministic interpretation of more and more of advanced quantum theory, including quantum field theory (see Cushing 1994). Suffice it to say, a deterministic interpretation of quantum theory is entirely coherent.

There remain two other controversial matters; which return us to general metaphysics and philosophy of science. First, should we apply the idea of determinism, as we have formulated it, to theories of the whole universe, that is, cosmologies? If so, then the ‘systems’ in question will be universes or ‘possible worlds’, that is, total possible courses of history. So one will in general not require that the systems whose states one compares must lie in the same possible world (see Possible worlds).

Second, should we accept the idea, for a given kind of system, of a complete theory, a theory that in some sense describes the whole truth about the systems? Some philosophers hold that this idea is incoherent: at least if it is filled out as allowing that such a theory is never formulated by humans; or at least if it allows that humans might be in principle incapable of formulating such a theory (see Scientific realism and antirealism §1). But if we accept some version of this idea, then we can reasonably talk of the systems, or perhaps the kind of system, being deterministic: namely, if and only if the systems’ final theory is deterministic.

So the cautious answer to these questions is No. To answer Yes is to be bold: (some would say, incoherent). In particular, if we answer Yes to both questions, we are in effect accepting that it is meaningful to talk of the whole

universe being deterministic. For we are accepting the idea of a complete theory of a given possible world (a total possible course of history). So we can reasonably call this theory the 'theory of the world', and its general propositions 'the laws of nature' (see Laws, natural §1). (Again, humans are unlikely to have much idea of this theory or its laws.) And then we can say that the given world is deterministic if and only if its theory is. That is, the given world is deterministic if and only if any two worlds, obeying this theory, that have exactly the same state (in the sense of this theory) as one another at a given time also have exactly the same state at all later times.

The rest of this entry is restricted to discussing determinism for given physical theories. It thereby answers No to the second question; and, cosmological theories apart, it also answers No to the first question. But before embarking on this cautious strategy, we should briefly note that, historically, the bold (perhaps incoherent) idea of the entire world being deterministic, irrespective of any theory, has been very important; it has been the focus of countless philosophers' discussions of determinism (both for and against it).

3 Defining determinism

In §2 we said that a theory is deterministic if and only if for any two systems of the kind described by the theory: if they are in exactly the same state as one another at a given time, then according to the theory, they will at all future times be in the same state as one another. But this formulation is still rough.

The main problem is that, whatever theory one considers, its systems are continually interacting with their environment: as physicists put it, no system is 'completely isolated'. For example, each system feels the gravitational pull of other objects. These interactions make determinism, as just formulated, an impossibly tall order. For, first, it will be very rare for two systems to be in exactly the same state at a given time. And even if they are, it will be virtually impossible that their subsequent interactions with their environments match so exactly that they are also in the same state as one another at all future times. But surely, determinism should not be so formulated that it will fail because of the vagaries of interactions with other systems: whether it fails or holds should be a matter internal to the theory considered.

The remedy is clear enough. To set aside such interactions, we need to formulate determinism in terms of completely isolated systems. But we cannot just think in terms of two systems in an otherwise empty universe. For in general the theory will take these two systems to interact with each other; so that again determinism can fail in a spurious way. That is to say, even if we suppose that at a given time the two systems are in the same state, at some future time they may well not be: their interaction, as described by the theory, might lead to their states differing. (The problem is of course aggravated if we think of the systems as also interacting in other ways, not described by the theory.)

To avoid this kind of spurious failure of determinism, we need to think of the theory as describing single completely isolated systems, each one alone in its universe. Let us say that a sequence of states for such a single system, that conforms to the laws of the theory, is a *model* of the theory. So a model contains a system of the theory's kind, undergoing a history allowed by the theory: the model is a 'toy universe' or 'toy possible world', according to the theory. (This use of 'model' is common in general philosophy of science. In particular, it is often useful to consider a scientific theory as the class of its models in this sense, rather than in the traditional manner of logicians - as a set of sentences closed under deduction; see Models; Theories, scientific.) Using this notion of model, we can give a better definition of determinism, which avoids the problem of interactions. We say that a theory is deterministic if and only if: any two of its models that agree at a time *t* on the state of their objects, also agree at all times future to *t*.

(This definition returns us to the first of the two questions at the end of §2: namely, should we apply the idea of determinism to theories of the whole universe, for example cosmologies? We now see that our strategy for avoiding spurious violations of determinism, due to interactions between systems, commits us to answering Yes to this question. For by taking a model of any theory to describe a single completely isolated system, alone in its universe, we are in a sense treating any theory as a cosmology. But since each of a theory's possible universes contains just one system of the kind treated by the theory, it is typically a humble, even a dull, cosmology!)

This definition is still a bit vague: precisely how should we understand a single time *t* in two models, and two models 'agreeing' on their states at *t*? The answers to these questions lie in the idea of isomorphism of models, or parts of models; in the usual sense used by logicians. (There is no need for a 'meta-time' outside the two models,

in terms of which their time series can be compared: thank goodness, since that would be very questionable!). Thus we can speak of an ‘instantaneous slice’ of one model (that is, the part describing the system at a single time) being isomorphic to an instantaneous slice of another model. And similarly, we can speak of isomorphism of ‘final segments’ of two models: that is, isomorphism of parts of two models, each part describing the system at all times future to some time within the model. Determinism is then a matter of isomorphic instantaneous slices implying that the corresponding final segments are isomorphic (where ‘corresponding’ means ‘starting at the time of the instantaneous slice’). That is: we say that a theory is deterministic if, and only if: for any two of its models, if they have instantaneous slices that are isomorphic, then the corresponding final segments are also isomorphic.

4 The notion of state

To a philosopher, our definition of determinism looks very formal. And indeed, it is closely related to purely mathematical questions. For a physical theory is often presented as a set of equations, so-called ‘differential equations’, governing how physical magnitudes (for example, numerically measurable quantities like distance, energy and so on) change with time, given their values at an initial time. Our definition then corresponds to such a set of equations having a unique solution for future times, given the values at the initial time; and whether a set of differential equations has a unique solution (for given initial values) is a purely mathematical property of the set.

But we should beware of identifying determinism with this purely mathematical property: there are conceptual, indeed metaphysical, matters behind the mathematics. The reason lies in the notion of state. We have taken states to be simply the properties ascribed by a theory to objects of a certain kind (the theory’s ‘systems’); and so as varying from one theory to another. But there are two general features which the notion of state needs to have if our definition of determinism is to be sure of capturing the intuitive idea. These features are vague, and cannot be formalized: but without them, there is a threat that our definition will be intuitively too weak.

First, states need to be intrinsic properties. It is notoriously hard to say exactly what is meant by ‘intrinsic’, but the idea is to rule out properties which might code information about how the future just happens to go, and thus support a spurious determinism. Thus, to take an everyday example, ‘Fred was mortally wounded at noon’ implies that Fred later dies. But the property ascribed at noon is clearly extrinsic: it ‘looks ahead’ to the future. And so this implication does not show that there is any genuine determinism about the processes that led to Fred’s later death.

Second, states need to be ‘maximal’, that is they need to be the logically strongest consistent properties the theory can express (compatibly with their being intrinsic). For in an intuitively indeterministic theory, there might well be some properties (typically, logically weak ones) such that models agreeing on these properties at one time implies their agreeing on them at all later times.

Do physical theories’ notions of state have these two features? The question is vague because there is no agreed analysis of the ideas of an intrinsic, or a maximal, property. Perhaps ‘maximal’ can be readily enough analysed in terms of logical strength, as just hinted. But it is notoriously hard to analyse ‘intrinsic’. But, by and large, the answer to this question is surely Yes. Physics texts typically define, or gloss, ‘state’ and similar words as a system’s maximal (or ‘complete’) set of intrinsic (or ‘possessed’) properties; and in philosophy, the most commonly cited examples of intrinsic properties are the magnitudes figuring in the states of familiar physical theories, such as mass or electric charge. So it seems there is no widespread problem of spurious satisfactions of determinism.

But although there is not a problem, the need for these features brings out the main point: determinism is not a formal feature of a set of equations. Indeed, there are many examples of a set of differential equations which can be interpreted as a deterministic theory, or as an indeterministic theory, depending on the notion of state used to interpret the equations.

The idea of states as intrinsic also brings out two other points, one philosophical and one technical. The philosophical point concerns the ideas at the end of §2 about laws of nature, and the whole universe (as against a given theory) being deterministic. One of course expects that making sense of the idea of laws of nature will involve the theory of properties. But we now see a more specific point: that making sense of the universe being deterministic will involve the general analysis of ‘intrinsic’.

The technical point concerns theories that treat all the states up to the given time, taken together, as contributing to

determining the future states. (There are a few such theories. It does not matter here whether all these earlier states taken together do determine all the future states: as, one might say, whether there is determinism of the future by the whole past.) At first sight, it looks as if such theories add to the usual intrinsic notion of state, a highly extrinsic notion - for which the state at a given time encodes some of the information in all earlier intrinsic states. What is going on?

In fact, in all such theories (so far as this author knows) the extrinsic notion is a technical convenience, rather than a new notion of state. The theory refers to the arbitrarily distant past (typically in some time-integral from minus infinity to the given time) just as a mathematically tractable way of stating information about the state at the given time, information that contributes to the future development of the system. (Wanting to state this information of course reflects the idea of states as maximal.) For example: in statistical physics, some such time-integrals define correlations in the present state; and in theories that study systems interacting with their environment, the past states of the system yield useful information about the present influence of the environment (which is otherwise not represented in the formalism).

Note that this explanation accords with a familiar tenet about causation: that past states influence the future, but only via their influence on the current state - there is thus no ‘action at a temporal distance’. This tenet is widely held by philosophers; and to the extent that one can talk about causation in physical theories, it is upheld in physics. This is especially true of relativity theory; for relativity both unifies space and time, and upholds the principle of contact-action (see Relativity theory, philosophical significance of §3; Spacetime). The tenet is also closely related to a very common property (being Markovian) of probabilistic theories, both in physics and beyond. Indeed, according to some probabilistic theories of causation, the tenet is equivalent to the theory being Markovian.

Theories that refer to past states are relevant to our final topic: the fact (mentioned in §2) that there are some uncontroversial variations on our definition of determinism. So far we have for simplicity assumed that there is a single intuitive idea of determinism: the idea of the present state determining future states. But as we have just seen, there is an analogous idea: that all the states up to the present, taken together, determine future states. It just so happens that (using an intrinsic, maximal notion of state!) this idea is not obeyed in known physical theories: they have no ‘action at a temporal distance’. But that is no reason to deny to the idea the name ‘determinism’; or, more clearly, ‘determinism of the future by the past’ (rather than by the present).

This point is reinforced by other analogous ideas, ideas which *are* obeyed in known physical theories. Thus in general relativity, and in quantum field theory, diverse technical reasons make it much easier to define a state on an interval of time (called a ‘sandwich’ of spacetime!) than at an instant of time (a ‘slice’ of spacetime). There is no hint here of action at a temporal distance: the interval can be arbitrarily short - it is just that for technical reasons it must have some duration. But such states prompt rather different definitions of determinism, requiring (roughly speaking) that for any interval, no matter how short, states to the future of that interval are determined by the state on it. And these definitions are often satisfied.

One can instead strengthen the definition of determinism, requiring the state at the given time to determine not only future states, but also past states. Many important physical theories have a property called ‘time-symmetry’ or ‘time-reversal invariance’, which implies that they satisfy this stronger definition, if they satisfy our first one. A famous example is Newtonian mechanics. Indeed, it may well be that Laplace had in mind this point (rather than just the intelligence having a memory), when he said in the quotation above ‘as the past’ (see Mechanics, classical; Thermodynamics §§4-5).

Development ethics

Development ethics is ethical reflection on the ends and means of socioeconomic change in poor countries and regions. It has several sources: criticism of colonialism and post-Second World War development strategies; Denis Goulet's writings; Anglo-American philosophical debates about the ethics of famine relief; and Paul Streeten's and Amartya Sen's approaches to development.

Development ethicists agree that the moral dimension of development theory and practice is just as important as the scientific and policy components. What is often called 'development' - economic growth, for instance - may be bad for people, communities and the environment. Hence, the process of development should be reconceived as beneficial change, usually specified as alleviating human misery and environmental degradation in poor countries.

Development ethicists do not yet agree on whether their ethical reflection should extend to destitution in rich *countries or aspects of North-South relations apart from development aid. Other unresolved controversies concern the status and content of substantive development norms. Finally, agreement does not yet exist as to how the benefits of and responsibilities for development should be distributed within and between countries.*

1 The nature of development ethics

National policy makers, project managers and international aid donors involved in development in poor countries often confront moral questions in their work. Development scholars recognize that social-scientific theories of 'development' and 'underdevelopment' have ethical as well as empirical and policy components. Development philosophers and other ethicists formulate ethical principles relevant to social change in poor countries, analyse and assess the moral dimensions of development theories and seek to resolve the moral quandaries raised in development policies and practice: In what direction and by what means should a society 'develop'? Who is morally responsible for beneficial change? What are the obligations, if any, of rich societies (and their citizens) to poor societies?

2 Sources

There are several sources for moral assessment of the theory and practice of development. First, beginning in the 1940s, activists and social critics - such as Gandhi in India, Raúl Prébisch in Latin America, and Frantz Fanon in Africa - criticized colonial and orthodox economic development (see Gandhi, M.K.; Fanon, F.). Second, since the early 1960s, American Denis Goulet, influenced by French economist Louis-Joseph Lebret and social scientists such as Gunner Myrdal, has argued that '"development" needs to be redefined, demystified, and thrust into the arena of moral debate' (1971: xix). Drawing on his training in continental philosophy, political science and social planning as well as on his grassroots experience in numerous projects in poor countries, Goulet was a pioneer in addressing 'the ethical and value questions posed by development theory, planning, and practice' (1977: 5). One of the most important lessons taught by Goulet (1971) is that so-called 'development', owing to its costs in human suffering and loss of meaning, can amount to 'anti-development' (see Berger 1974).

A third source of development ethics is the effort of Anglo-American moral philosophers to deepen and broaden philosophical debate about famine relief and food aid. Beginning in the early 1970s, often in response to Peter Singer's utilitarian argument for famine relief (1972) and Garrett Hardin's 'lifeboat ethics' (1974), many philosophers debated whether affluent nations (or their citizens) have moral obligations to aid starving people in poor countries and, if they do, what are the nature, bases and extent of those obligations (see Aiken and LaFollette (eds) 1976). By the early 1980s, however, moral philosophers, such as Nigel Dower, Onora O'Neill and Jerome M. Segal, had come to agree with those development specialists who for many years had believed that famine relief and food aid were only one part of the solution to the problems of hunger, poverty, underdevelopment and international injustice. These philosophers have argued that what is needed is not merely an ethics of aid but a more comprehensive, empirically informed, and policy relevant 'ethics of Third World development'. The kind of assistance and North-South relations called for depend on how (good) development is understood.

A fourth source of development ethics is the work of Paul Streeten and Amartya Sen. Both of these economists have addressed the causes of global economic inequality, hunger and underdevelopment, and attacked these problems with, among other things, a conception of development formulated explicitly in terms of ethical

principles. Building on Streeten's 'basic human needs' strategy (1981), Sen argues that development should be understood ultimately not as economic growth, industrialization or modernization, which are at best means (and sometimes not very good means), but as the expansion of people's valuable capabilities and functionings: 'what people can or cannot do, e.g., whether they can live long, escape avoidable morbidity, be well nourished, be able to read and write and communicate, take part in literary and scientific pursuits, and so forth' (1984: 497) (see Nussbaum and Sen (eds) 1993; Nussbaum and Glover (eds) 1995).

These four sources have been especially influential in the work of Anglo-American development ethicists. When practised by Latin Americans, Asians, Africans and non-Anglo Europeans, development ethics often draws on philosophical and moral traditions distinctive of their cultural contexts (see, for example, Luis Camacho (1993) on Costa Rica, and Godfrey Gunatilleke (1988) on Asia).

3 Areas of consensus

Although differing on a number of matters, development ethicists exhibit a wide consensus about the commitments that inform their enterprise, the questions they are posing and the unreasonableness of certain answers. Development ethicists typically ask the following related questions. What should count as (good) development? Should we continue using the concept of development instead of, for example, 'progress', 'transformation', 'liberation', or 'postdevelopment alternatives to development' (Escobar 1995)? What should be a society's basic economic, political and cultural goals and strategies, and what principles should inform their selection? What moral issues emerge in development policy making and practice and how should they be resolved? How should the burdens and benefits of development be conceived and distributed? Who or what should be responsible for bringing about development? A nation's government, civil society or the market (see Market, ethics of the)? What role - if any - should more affluent states, international institutions, and nongovernmental associations and individuals have in the self-development of poor countries? What are the most serious local, national and international impediments to good development? To what extent, if any, do moral scepticism, moral relativism, national sovereignty and political realism pose a challenge to this boundary-crossing ethical inquiry? Who should decide these questions and by what methods (see Moral expertise)?

In addition to accepting the importance of these questions, most development ethicists share ideas about their field and the general parameters for ethically-based development. First, development ethicists contend that development practices and theories have ethical dimensions and can benefit from explicit ethical analysis and criticism. Second, development ethicists tend to see development as a multidisciplinary field with both theoretical and practical components that intertwine in various ways. Hence, they aim not merely to understand development, conceived generally as desirable social change, but also to argue for and promote specific conceptions of such change. Third, although they may understand the terms in somewhat different ways, development ethicists are committed to understanding and reducing human deprivation and misery in poor countries. Fourth, a consensus exists that development projects and aid givers should seek strategies in which both human wellbeing and a healthy environment jointly exist and are mutually reinforcing (Engel and Engel (eds) 1990). Fifth, these ethicists are aware that what is frequently called 'development' - for instance, economic growth - has created as many problems as it has solved. 'Development' can be used both descriptively and normatively. In the descriptive sense, 'development' is usually identified as the processes of economic growth, industrialization, and modernization that result in a society's achieving a high (per capita) gross domestic product. So conceived, a 'developed' society may be either celebrated or criticized. In the normative sense, a developed society, ranging from villages to national and regional societies, is one whose established institutions realize or approximate (what the proponent believes to be) worthwhile goals - most centrally, the overcoming of economic and social deprivation. To avoid confusion, when a normative sense of 'development' is meant, the noun is often preceded by a positive adjective such as 'good' or 'ethically justified'.

A sixth area of agreement is that development ethics must be conducted at various levels of generality and specificity. Just as development debates occur at various levels of abstraction, so development ethics should assess (1) basic ethical principles, (2) development goals and models such as 'economic growth', 'growth with equity', 'basic needs' and, in the1990s, 'sustainable development', 'structural adjustment' and 'human development' (United Nations Development Programme), and (3) specific institutions and strategies.

Seventh, most development ethicists believe their enterprise should be international in the triple sense that the

ethicists engaged in it come from many nations, including poor ones; that they are seeking to forge an international consensus; and that this consensus emphasizes a commitment to alleviating worldwide deprivation.

Eighth, although many development ethicists contend that at least some development principles or procedures are relevant for any poor country, most agree that development strategies must be contextually sensitive. What constitutes the best means - for instance, state provisioning, market mechanisms, civil society and their hybrids - will depend on a society's history and stage of social change as well as on regional and global forces.

Ninth, this flexibility concerning development models and strategies is compatible with the uniform rejection of certain extremes. For example, most development ethicists would repudiate two models: (1) the maximization of economic growth in a society without paying any direct attention to converting greater opulence into better human living conditions for its members, what Sen and Jean Drèze call 'unaimed opulence', and (2) an authoritarian egalitarianism in which physical needs are satisfied at the expense of political liberties.

4 Controversies and agenda

In addition to these points of agreement, there are several divisions and unsettled issues. A first unresolved issue concerns the scope of development ethics. Development ethics originated as the 'ethics of Third World Development'. There are good reasons to drop - as a Cold War relic - the 'First-Second-Third World' trichotomy. There is no consensus, however, on whether or not development ethics should extend beyond its central concern of assessing the development ends and means of poor societies.

Some argue that development ethicists should criticize human deprivation wherever it exists and that rich countries, since they too have problems of poverty, powerlessness, and alienation, are 'underdeveloped' and, hence, fall properly within the scope of development ethics. Perhaps the socioeconomic model that the North has been exporting to the South results in the underdevelopment of both. Others contend that since development ethicists address questions of rich country responsibility and global distributive justice, they should not restrict themselves to official development assistance but should also treat international trade, capital flows, migration, environmental pacts, military intervention, and responses to human rights violations committed by prior regimes. The chief argument against extending the boundaries in these ways is that development ethics would thereby become too ambitious and diffuse. If development ethics grew to be identical with all social ethics or all international ethics, the result might be that insufficient attention would be paid to alleviating poverty and powerlessness in *poor* countries. Both sides agree that development ethicists should assess various kinds of North-South (and South-South) relations with respect to their effects on economic and political inequality in poor countries. What is unresolved, however, is whether development ethics also should address such topics as the ethics of trade, military intervention and international institutions.

Development ethicists are divided also on the status of the moral norms that they seek to justify and apply. Three positions have emerged. Universalists, such as utilitarians and Kantians, argue that development goals and principles are valid for all societies (see Universalism in ethics §3; Utilitarianism; Kantian ethics). Particularists, especially communitarians and postmodern relativists, reply that universalism masks ethnocentrism and (Northern) cultural imperialism (see Community and communitarianism; Postmodernism). Pro-development particularists either eschew all universal principles or affirm only the *procedural* principle that each nation or society should draw only on its own traditions and decide its own development ethic and path. (Anti-development particularists, rejecting both change brought from the outside and public reasoning about social change, condemn all development discourse and practice.) A third approach - advanced, for example, by Martha Nussbaum, Jonathan Glover, Seyla Benhabib and David Crocker - tries to avoid the standoff between the first two positions (see Nussbaum and Glover (eds) 1995). On this view, development ethics should forge a cross-cultural consensus in which a society's own freedom to make development choices is one among a plurality of fundamental norms and in which these norms are of sufficient generality so as not only to permit but also to require sensitivity to societal differences (see Moral pluralism).

Next is a question related to the universalism-particularism debate: to what extent, if any, should development ethicists propose visions committed to a certain conception of human wellbeing, and how 'thick' or extensive should this vision be? There is a continuum here: at one end, there is more commitment to the values of individual choice, tolerance of differences, and public deliberation about social ends and means; and, at the other, more

normative guidance about the good human life but less room for individual and social choice.

Supposing that development principles should have some substantive content (beyond the procedural principle that each society or person should decide for itself), there are disagreements about that content. Assuming that social development concerns human development, with what moral categories should it be conceived? Candidates include: utility (preference satisfaction); social primary goods, such as income; negative liberty; basic human needs; autonomy; valuable capabilities and functionings; and rights. Although some think that a development ethic ought to include more than one of these moral concepts, development ethicists differ with respect to which ones to embrace and how to relate them. One alternative would be to work out a concept of human wellbeing that combines, on the one hand, a Neo-Kantian commitment to autonomy, critical dialogue and public deliberation with, on the other hand, neo-Aristotelian beliefs in the importance of physical health and social participation. Development duties might then flow from the idea that all humans should have a right to at least a minimal level of wellbeing.

There is also an ongoing debate about how development's benefits, burdens and responsibilities should be distributed within poor countries and between rich and poor countries. Utilitarians prescribe simple aggregation and maximization of individual utilities. Rawlsians advocate that income and wealth be maximized for the least well-off (individuals or nations) (see Rawls, J.). Libertarians contend that a society should guarantee no form of equality apart from equal freedom from the interference of government and other people. Capabilities ethicists defend governmental responsibility to enable everyone to be able to advance to a level of sufficiency with respect to the valuable functionings.

Development ethicists also differ with respect to whether (good) social development should have - as an ultimate goal - the promotion of values other than the present and future human good. Some development ethicists ascribe intrinsic value, equal to or even superior to the good of individual human beings, to human communities of various kinds, for instance, family, nation or cultural group. Others argue that nonhuman individuals and species, as well as ecological communities, have equal and even superior value to human individuals (see Animals and ethics). Those committed to 'ecodevelopment' or 'sustainable development' do not yet agree on what should be sustained as an end in itself and what should be maintained as an indispensable or merely helpful means (see Environmental ethics). Nor do they agree on how to surmount conflicts among intrinsic values.

Dewey, John (1859-1952)

The philosophy of John Dewey is original and comprehensive. His extensive writings contend systematically with problems in metaphysics, epistemology, logic, aesthetics, ethics, social and political philosophy, philosophy and education, and philosophical anthropology. Although his work is widely read, it is not widely understood.

Dewey had a distinctive conception of philosophy, and the key to understanding and benefiting from his work is to keep this conception in mind. A worthwhile philosophy, he urged, must be practical. Philosophic inquiry, that is, ought to take its point of departure from the aspirations and problems characteristic of the various sorts of human activity, and an effective philosophy would develop ideas responsive to those conditions. Any system of ideas that has the effect of making common experience less intelligible than we find it to be is on that account a failure. Dewey's theory of inquiry, for example, does not entertain a conception of knowledge that makes it problematic whether we can know anything at all. Inasmuch as scientists have made extraordinary advances in knowledge, it behoves the philosopher to find out exactly what scientists do, rather than to question whether they do anything of real consequence.

Moral philosophy, likewise, should not address the consternations of philosophers as such, but the characteristic urgencies and aspirations of common life; and it should attempt to identify the resources and limitations of human nature and the environment with which it interacts. Human beings might then contend effectively with the typical perplexities and promises of mortal existence. To this end, Dewey formulated an exceptionally innovative and far-reaching philosophy of morality and democracy.

The subject matter of philosophy is not philosophy, Dewey liked to say, but 'problems of men'. All too often, he found, the theories of philosophers made the primary subject matter more obscure rather than less so. The tendency of thinkers is to become bewitched by inherited philosophic puzzles, when the persistence of the puzzle is a consequence of failing to consider the assumptions that created it. Dewey was gifted in discerning and discarding the philosophic premises that create needless mysteries. Rather than fret, for instance, about the question of how immaterial mental substance can possibly interact with material substance, he went to the root of the problem by challenging the notion of substance itself.

Indeed, Dewey's dissatisfaction with the so-called classic tradition in philosophy, stemming at least from Plato if not from Parmenides, led him to reconstruct the entire inheritance of the Western tradition in philosophy. The result is one of the most seminal and fruitful philosophies of the twentieth century.

1 Life

Dewey was born in Burlington, Vermont in 1859. He earned his BA degree at the University of Vermont, where he was particularly drawn to Scottish common-sense realism. He took his Ph.D. at the Johns Hopkins University, writing his dissertation on the psychology of Kant. At Hopkins he was much influenced by the experimental psychology of G. Stanley Hall, but he was taken above all by the philosophy of Hegel, taught by George Sylvester Morris. Hegel's philosophy, Dewey later said, answered his craving for a unified vision of reality, as distinguished from dualistic and reductive philosophies and those that were content with providing isolated analyses of particular phenomena.

After holding appointments at the University of Michigan and the University of Minnesota, he moved to the University of Chicago in 1894, where he was head of the Department of Philosophy, Psychology and Pedagogy. There he founded the University Elementary School (better known as the Laboratory School or the Dewey School), where he introduced experimental educational practices that both stemmed from and modified his philosophy of education. During this period Dewey began a decided shift away from Hegelian idealism in the direction of his naturalistic experimentalism. In 1904 he moved to Columbia University in New York City, where he developed his mature philosophy. He retired in 1930 but continued to teach as Professor Emeritus at Columbia until 1939. Thereafter he continued to be active, mostly in New York City, until his death in 1952.

Dewey's production of philosophic works was prodigious: forty books and more than 700 articles. After the death of William James in 1910, he was without peer in philosophy in the USA and became a figure of exceptional national and international prominence. He was frequently invited to lecture abroad; he did so in Mexico, China,

Japan, Turkey, France, Scotland and the USSR. He was called to several major lectureships, including the Carus Lectures in 1922, the Gifford Lectures in 1929, the William James Lecture in 1930 and the Terry Lectures in 1934. He received honorary degrees from several major universities world-wide and was a founder and the first President of the American Association of University Professors and President of the American Philosophical Association.

Inasmuch as he took seriously the notion of philosophy as a guide to conduct, it was fitting that he devoted much of his time to practical causes. He took a leading role in numerous associations devoted to political and educational reforms, and at the same time contributed frequently to public discourse in such journals of opinion as *The New Republic*, *Commentary*, *The Nation* and *Christian Century*. In 1937, at the age of 78, he accepted the chairmanship of the Commission of Inquiry to investigate the charges of Josef Stalin against Leon Trotsky. The question of Trotsky's guilt or innocence was secondary to the question of whether Stalin was the leader of a great democratic and economic revolution or the perpetrator of massive and brutal oppression. Dewey and the Commission found Trotsky not guilty and Stalin guilty, for which he was viciously criticized by a host of intellectuals sympathetic to Stalin.

2 Philosophical anthropology

Dewey's thinking about human nature is profoundly indebted to the theory of biological evolution as well as to James' *Principles of Psychology* (1890), which itself owed much to the Darwinian view. The classical idea of species implies changeless essence. It was also taken to imply that there is a perfectly definite end and station in life that each human being ought to achieve in order to fulfil their nature. Darwin's theory that species come into existence and undergo change was, therefore, truly revolutionary: the potentialities of human nature are not fixed, and there is no predetermined outcome or definite social role towards which each and every person ought to aim (see Darwin, C.R. §§2-3; James, W. §2).

According to the Darwinian conception, the human being is not understood primarily as a spectator of nature, but as a participant in it. Like any living organism, we are caught up in processes of change whose tendencies are fateful for our weal and woe. All human practices and aims are conceived with this assumption foremost in mind. Any form of human endeavour - including moral, cognitive and artistic activity - is elucidated as a mode of practice in which the individual acts with multiple agencies of the surrounding environment. Any experience is a conjoint effect of the organism and environment acting together, rather than a passive registration of external stimuli.

Dewey's notion of habit is fundamental to his analysis of human nature. A habit is not the private possession of an individual. It is the product of interactions inclusive of organism and environment, in which the resultant habit is determined as much by particular features of the environment as by the impulses of the organism. The habits appropriate to agricultural practice, for example, could not arise in the individual in isolation from the conditions in which farming occurs. The soil, the seasons and the elements dictate forms of action as much as the physiological and intellectual capacities of the farmer. The habits of farming are a collaborative result of organism and environment.

An impulse by itself does not constitute a form of action. It is plastic, and a formed habit of thought or action can only result from interaction. Dewey believed that a person's nature can take a plurality of possible forms, depending on environmental conditions. While he acknowledged that there are native differences in human beings, Dewey regarded such variations as highly malleable and subject to change as a consequence of learning. For everyone, then, there are multiple opportunities and possible directions for growth. Growth implies that our basic dispositions, our virtues, intelligence, talents and traits of personality are subject to the formations of home, school, church and every manner of human association. It is no surprise, then, that Dewey devoted so much study and experiment to the practice of education.

There is no mind or self antecedent to the formation of habit. The self, according to Dewey, is a dynamic complex of habits. It is an outcome, not an original existence. Mind consists of habits. Every idea is a habit of action; it is an anticipation of definite ways of behaving. The idea of a table, for example, consists of all the ways one can act with the object so designated. To have an idea of a table is not necessarily to have an image, nor is it to envisage the inherent essence of tablehood. It is to be prepared to act with such objects in ways to bring about predictable outcomes. Such outcomes are originally learned by means of active participation with objects, hence mind is

derivative of behaviour. But the meanings which constitute mind are mostly (perhaps exclusively, Dewey sometimes seems to say) provided by language. Language, too, is derivative of conduct, but it is necessarily social conduct. The public meanings conveyed by language could not arise except in shared activity with shared features of an environment. According to Dewey's thinking, consequently, mind can arise only within a social condition. Actual thinking is a function of acquired habits and the promptings of a specific situation.

In accordance with these conceptions, Dewey distinguished a form of conduct that could be common to all human activities. This form he called, generically, art. It is a deliberate practice with the environment, by means of which an individual transforms conditions that are initially disordered and troubling into a situation that is unified and directed. The individual must identify the nature of the problematic conditions, formulate possible plans of action that would utilize the instrumentalities of the particular situation, and execute the plan that seems to hold most promise for success. In conduct as art, individuals move from an initial condition of alienation from the environment to one in which they have effectively engaged their powers with those of their surroundings and have brought the two to consummation. Dewey thought that conduct of this sort characterizes all forms of effective activity. This type of conduct is natural to a living being striving to cope with processes of change, and it provides a consummation of effort that human beings find intrinsically fulfilling (see Pragmatism §1; Anthropology, philosophy of).

3 Metaphysics

Dewey did not think of metaphysics as a foundational discipline, conjuring up principles to certify value judgments and cognitive claims. On the contrary, he was very critical of metaphysics which had such pretensions; such endeavours were part of the obnoxious heritage of the classic tradition.

The classic tradition originating in ancient Greek philosophy is above all characterized by the assumption of disparate realms of being, Dewey contended. These realms are conceived in notably different ways, but they have in common the belief that there is a world of 'true' being, the most real being: that of changeless perfection, which is juxtaposed to a world of becoming, where all things come into existence, undergo change and pass away. The classic notion of being is not only false but pernicious, for it provides the rationale for moral absolutes, whose actual effect is to demand a conformity that is injurious to human flourishing (see Plato §10).

A universal assumption of the reigning tradition, Dewey observed, was that true being is conceived as the object of rational knowledge as such. That alone is the really real. Prior philosophies accordingly had been typically reductive, declaring with the idealists, for example, that reality *per se* is nothing but a rational order of ideas, or with the materialists that nature is nothing but matter in motion, possessing none of the other traits commonly experienced: such fateful events as immediate quality, disorder and ends. With these reductive assumptions, philosophers attributed to subjective mind within itself the plural and varying properties that would otherwise be predicated of nature (see Idealism §1; Materialism §3).

Dewey's metaphysical thought is an attempt to restore to the world the integrity of which philosophers had divested it. He provides a characterization of the most prominent features of the natural world in their continuities with human experience. This is a world of becoming, in the classic vernacular; there is no changeless being. Such phenomena as experience, human nature, mind, knowledge, art and value are conceived as natural functions of the biological organism interacting with an environment marked by change, order and disorder, obstacles, instrumentalities and episodic fulfilments.

The restoration of integrity of vision is consequent upon the continuity of experience and nature. We experience real events in their relations to ourselves and to each other. We accept our experience as disclosing real traits of the world. The varying qualities of events are natural functions. Not only are sensations of colours and sounds the outcomes of natural processes, but also the full panoply of characteristics that we refer to with such predicates as 'lovely', 'hateful', 'wicked' and 'admirable'. Genuine potentialities of nature are thus exhibited. The potentiality is neither in the organism alone nor in the object alone, but in the situation inclusive of both.

With such assumptions, Dewey insists, for example, on the reality of what he calls the precarious: events that are threatening, disordered, baffling and the like, which were formerly excluded from the really real. We experience such things as terrorist attacks, avalanches, lost keys, droughts and stubbed toes. These are not simply mental occurrences, unrelated to nature. They are public phenomena, and if we cannot accord them appropriate

ontological status, philosophy can offer no clue as to how we can contend with them.

Qualitative change, likewise, is as real as anything else and it is one of the traits of nature that Dewey discerned and analysed with telling effect. He calls these changes ‘histories’. Phenomena that had been regarded in the classic tradition as original entities or substances are treated by Dewey as the outcomes of histories. Mind, intelligence, knowledge, human nature and moral and aesthetic values are such outcomes. Dewey frequently analysed them in detail, believing that to possess knowledge of such change is invaluable in contending deliberately and effectively with the processes in which we are mortally implicated.

A further significant trait is what Dewey calls ‘the stable’. This expression refers not only to conditions that are relatively constant and enduring, but, fundamentally, to the correlations between processes of change. So-called laws of nature are not self-subsistent beings; they are the correlations between one process of change and another, as are those involving pressure and temperature in an enclosed volume of gas, for example. Both pressure and temperature undergo change, and the change in one is correlated in a measurable and predictable way with change in the other. As such correlations are determined, it becomes possible to introduce deliberate variations in natural events for the sake of directing them to predictable outcomes. Knowledge, then, is neither a direct grasp of essences nor a summary of antecedently received sensations. It is an instrument for directing processes of change.

The purpose of Dewey’s metaphysics is practical. Its main intent, he declared, is to exhibit the nature and function of intelligence. Contrast the classic model with Dewey’s: if the nature of the world is thought to be morally and cognitively determined by a pattern of changeless perfection, then the role of intelligence is to attain a direct grasp of such principles. Subsequently, events in the world of becoming are classified as conforming or not conforming to the antecedent pattern. This is a classificatory and deductive logic, formalized by Aristotle. According to such a logic, moral action consists of the attempt to constrain processes of change to conform to the antecedent absolute. If, however, the object of knowledge is the correlation between processes of change, and if the constituents of these processes can be varied, then it becomes possible to direct such processes towards welcome fulfilments. This procedure Dewey calls ‘experimental logic’. These are distinctly different procedures of practical action, and if the assumptions of the classic tradition are false, then conduct is pointlessly straitjacketed. When Dewey says it is the task of philosophy to characterize the nature of things in a way that illuminates possible harmonies between our ambitions and aspirations and the realities of the world, he has in mind the substitution of an experimental logic for the stultifying anachronisms of the classic tradition (see Processes §4; Whitehead, A.N. §4).

4 Theory of inquiry

The heart of Dewey’s pragmatism - or ‘instrumentalism’, as he preferred - is his theory of inquiry. It is most significant that the explicit guiding assumption of this theory is that logical distinctions and methods of inquiry develop out of the process of problem-solving activities. The logic of inquiry is not a set of norms existing independently of and prior to our cognitive efforts. Rather, procedures and logical distinctions introduced by inquirers prove themselves in their successes in resolving cognitively problematic situations. ‘Successful’ is not to be defined by philosophers, but by the aims of modern science itself, which Dewey took to be the prediction and control of natural phenomena. Ultimately at stake in disputes about the nature and possibility of knowledge is the capacity of human beings to act in concert with ongoing events. Such action is dependent upon the determination of how changes in one process are correlated with changes in another.

Science, then, does not get its credentials from philosophy. Instead, the philosopher studies science for a number of worthy purposes: to understand the nature of effective inquiry, the nature of the valid object of knowledge and the possible extensions of scientific methods to domains of problem-solving that are not exclusively scientific. Dewey also appropriates scientific results as indispensable constituents in his particular analyses of human nature, social processes and methods of education. (This is not to say that scientists themselves do not sometimes misunderstand the nature of their own activity, as Dewey on occasion points out.)

According to any philosophy at the turn of the twentieth century, all experience is exclusively subjective: it takes place within the mind, rather than being a consciousness of events external to the sentient being. Traditional dualistic epistemology, then, treats experience as a private, self-enclosed domain that is only problematically (if at all) related to anything beyond itself. Epistemologists laboured to conceive how a purely subjective mental event might possibly correspond to something external to it. If experience is continuous with nature, however, the real

problem is of an entirely different sort: to determine how variations in one natural and public event (or set of events) are related to variations in other such events.

This is a problem not for philosophers, but scientists, and scientists have proved very successful in reaching such determinations. They perform experiments and make observations in accordance with a hypothesis. The hypothesis states that if specified changes are introduced under controlled conditions, predictable effects will ensue. If the inquiry is conducted as the hypothesis prescribes, and if the effects occur as predicted, then the hypothesis is tentatively confirmed. Dewey always insisted that warrant for the putative knowledge is dependent upon confirmation from the community of relevant inquirers. Such warrant is always a matter of degree and it is always fallible.

Inquiry involves the deliberate manipulation of the conditions within which it occurs. The very subject matter of the investigation might be controlled, as in laboratory work; or the conditions of observation might be controlled, as in astronomy. In any case, the inquirer introduces deliberate change in the cognitive situation in order to produce the object of knowledge.

The object of knowledge as such is the outcome of a process; it does not exist antecedently to inquiry. Natural events, with their own potentialities, powers and limitations, exist prior to inquiry, of course, but they do not in that condition constitute an object of knowledge. When such an object is produced, its character is dependent upon the specific conditions of inquiry that have been introduced, including the subject matter under scrutiny. The investigator has responded to a specific problematic situation, has contrived an inquiry of a particular sort, and makes observations and measurements in terms of concepts that are largely characteristic of the existing state of the science. Inquiry is inevitably theory-laden - or, in Dewey’s parlance, meaning-laden. Inquiry constitutes, in identifiable and specifiable ways, a transformation of antecedent subject matter.

Inasmuch as Dewey regards the object of knowledge as a deliberate construction, some readers have concluded that he is an antirealist. This conclusion is mistaken. Dewey repudiated the archaic idea that knowledge is a correspondence between an object and a mental image, but that does not make him an antirealist. Indeed, whatever ‘realism’ is taken to mean, Dewey’s study of inquiry concludes that our ideas are determined by the nature of real events to a far greater extent than was recognized in any pre-pragmatic philosophy. The meaning of any object consists of the conception of all that object can do in relation to other objects. In other words, we know how objects function as constituents of processes of change; and in that form alone can we utilize them for practical purposes. Mere images cannot do so; nor can Platonic forms or Cartesian essences. Our conceptual systems, moreover, have arisen from the very processes of effective inquiry. Although our concepts are subject to revision, it can hardly be said that they are arbitrary impositions on nature. While it must be insisted that the successes of science are always open to refinement and revision, it is unmistakable that our ability to function with formerly inscrutable and overwhelming natural powers has undergone astounding advancement. Dewey calls this shift a revolution from arts of acceptance to arts of control (see Scientific realism and antirealism §4).

5 Moral philosophy: the construction of good

The classic tradition has supposed the existence of something essentially changeless and perfect in the nature of things, ranging from Platonic forms to natural law, and from Kantian reason to the nature of the Absolute. Even utilitarianism shares in that tradition in supposing a single criterion of good, as does Marxism in holding that there is but a single pattern that describes all historical change. Many philosophers have thought that they espy a moral absolute; and many have believed that such an absolute is of supreme value in human conduct. Many others would like to agree, but they have despaired of discerning such a rationally incontrovertible standard.

The classic tradition assumes a changeless principle or goal for all moral action, yet the real world is marked by change. It presents the continuing occurrence of unique situations, each of which can yield a variety of possible outcomes. There is likewise an indefinite plurality of human possibilities. Adherence to the classic tradition, then, constitutes a demand for unyielding conformity to prevailing cultural requirements, which are given a specious authority by religious or philosophic speculations. The tradition enforces conditions in which human possibilities are denied for the sake of maintaining precedent, custom or arbitrary authority. Historically, the feudal system has been the most prominent example. The contemporary demand that women and men should not be confined to their traditional roles is, in effect, a repudiation of the classic tradition.

As Dewey conceived it, the moral life is suffused with innumerable possibilities of enjoyment and happiness, as well as of disaster. Ordinary life revolves around familiar attachments, ambitions and fears. The philosophic task, Dewey believed, is to place at the disposal of human beings the assumptions and methods that would facilitate the efforts in which they will be engaged in any case. It is a project of enabling and liberating. Each situation might be approached to identify its unique opportunities for fulfilment. The precarious values of the situation might be clarified and united into more inclusive wholes and made more secure against obstacles and threats.

This procedure Dewey calls the 'construction' of good. No phrase encapsulates so well both his opposition to the classical tradition and his alternative to it. Rather than conform to an antecedently given pattern of right conduct, one actively constructs a new situation, intending to discriminate its particular tendencies and to contrive a consummation of the energies of the organism and environment - the practice referred to in §3 as 'conduct as art'. Dewey can be eloquent in characterizing such experience as one of deeply enriched qualities and cherished meanings. It is a cumulative experience, enhancing human powers. The continuation of this process over time Dewey denominates 'growth'.

There is no absolute consummation in life, nor any exact station determined a priori by one's nature. Rather, one may treasure the very process of conduct as art. Dewey says that growth itself is the only moral end, and he identifies it primarily as a social process. Our behaviour is characteristically interpersonal; as such, it is the source of most of our learning, and our participation with others is the source of our most profound satisfactions. As a constituent of growth, 'shared experience is the greatest of human goods'. The construction of good is typically a shared activity, greatly facilitated by deliberate cooperation.

The activity requires appropriate habits of thought and conduct, including those of communication and cooperation. Above all, Dewey believes, it requires the habits of experimental inquiry. The situations to be transformed are often of a complex and comprehensive nature, such as, for example, the reconstruction of educational institutions; so we must possess reliable knowledge of how such practices actually work. We must also possess the imaginative habits of the experimenter to formulate hypotheses about how such conditions might be reconstructed. We might hypothesize that certain innovations in practice would eventuate, say, in more alert, reflective and well-motivated students. The hypothesis guides conduct by prescribing the changes that would effect such results: the introduction of specified procedures would transform educational activity in such a way as to produce the desired outcomes. This is the manner in which scientific hypotheses guide conduct, not - by contrast - in deducing a prescription for action from an alleged moral absolute. That would be a reversion to the logic of the classical tradition (see Pragmatism in ethics §3).

6 Moral philosophy: the democratic way of life

Dewey was convinced that modern society is swamped in the modes of thought inherited from the classic tradition. Instead of using experimental logic, we depend on putative moral absolutes. Our conduct is governed, in effect, by precedent, which largely represents, according to Dewey, the entrenched prerogatives of privileged groups. The most beneficent change that could be introduced into society, consequently, would be the teaching and widespread adoption of experimental habits of thought (see Education, history of philosophy of §9). We would not just address our several problematic situations with greater promise of success, but we would re-evaluate our economic and political behaviour with a view to what that behaviour really does and to what any alternatives to it might do.

Dewey sometimes called deliberation and action of this sort 'social intelligence' and sometimes 'democracy as a way of life'. Democracy as a way of life, he said, could be a norm for all forms of human association. Surprisingly, Dewey never provided a systematic exposition of the norms of this life, but its constituents can be extracted from his writings. It consists of several habits or virtues, foremost among them experimental habits of inquiry. These include fallibilism, rather than dogmatism, and an insistence that we follow the evidence of inquiry wherever it leads, rather than cling to preconceived ideas. Experimentalism implies both a willingness to entertain novel hypotheses and the personal flexibility to try out unaccustomed modes of action. The dissemination of the results of inquiry as widely as possible is also indispensable to the democratic ethos.

Democratic life, as Dewey conceives it, also implies respect for persons. Respect of this sort does not entail policy prescriptions, but it means that every person has a right to participate in the formation of goods. It implies that individuals should be seriously receptive to each other's concerns, taking them into account - at least initially - as

deserving an honest hearing. It also implies that persons communicate with each other freely and honestly to convey their concerns and to propose their tentatively preferred plans of action. Out of such virtue and discourse, leavened with scientific knowledge, shared proposals for action would emerge and would be honoured. It should go without saying that democratic virtue excludes deliberately antisocial behaviour.

On a small scale, these procedures are familiar. In our personal relations - friendships, marriages and voluntary associations of all kinds - we do not presume to enforce our views on other participants in a unilateral way. We assume that there will be differences of opinion, great and small, and we typically assume that we will talk these problems over in a civil manner and try to arrive at some more or less amicable agreement about what to do. We do not always succeed in doing so, but when we fail, we do not generally bolt the association. Our common activities are usually too precious for anything so shortsighted. Our treasured relationships do not survive such intransigence. Dewey believed that the virtues exhibited in such relations might be extended to incorporate much wider groups.

No philosopher before Dewey had conceived moral discourse as essentially communicative. The democratic virtues, after all, are impertinent to the various incarnations of the classic tradition. If the good and the right are known absolutely, the discourse of social intelligence is superfluous. One must concede that such discourse does not guarantee that consensus will always occur. Conflict and frustration are inevitable; but Dewey believed that they would be substantially less than they are when immovable oppositions are generated by moral absolutes.

The disciplines of the democratic way of life are demanding, and they can easily be corrupted. Dewey urged that schooling of all kinds incorporate the procedures of cooperative intelligence as a matter of routine. Indeed, all forms of association might be conducted in a manner to make democratic values habitual. Were such favourable conditions to exist, he thought, this way of life could be reasonably approximated.

It is a way of life that can be criticized for providing insufficient finality to moral judgment. It is true: the democratic/scientific virtues do not ensure the unanimity craved by adherents to the classic tradition. On the other hand, their exercise precludes the source of most of our torments: deliberately hurtful conduct. And it promises a release of human possibilities from needless subservience to moral absolutes. In fact, the verdict on Dewey's moral philosophy might be that it makes excessive demands of human flesh, not that it is too permissive. In any case, if the classic tradition is indeed a relic, then perhaps Dewey's thought points the way to a more pertinent philosophy than any other currently offered to our candid judgment (see Social democracy §2).

Dharmakīrti (*c.*600-60)

Dharmakīrti represents the philosophical apex of the Buddhist contribution to Indian thought of the post-systematic period. On the basis of Dignāga's late works he developed a system of epistemology with a strong emphasis on logic, propounding it both as an explanation and defence of Dignāga's thought. His logic, particularly, was new; in order to create a system of Buddhist logic proper, it clearly established the general Indian idea that logical relations are founded in reality. Buddhist epistemology as shaped by Dharmakīrti became a strong and influential rational tradition in late Indian Buddhism and has been studied and continued in Tibet up to the present time.

1 Writings

According to legend, Dharmakīrti was born a South Indian Brahman and taught at the monastic 'university' of Nālanda. He was a pupil of Īśvarasena and, in the words of the Chinese pilgrim Yijing, 'brought further progress in the field of logic after Dignāga' ([671-95] 1966: 182). He was also an acknowledged poet. The later Buddhist tradition followed Dharmakīrti's interpretation of Dignāga, and he strongly influenced the Brahmanical logicians as well. His theories have been studied and transmitted by Tibetan epistemologists and logicians up to the present time and remain part of the traditional higher education curriculum in Tibet.

Possibly all Dharmakīrti's philosophical works, four major and three minor, are extant in their original Sanskrit in China, but due to the inaccessibility of these sources, in the case of the *Pramāṇaviniścaya* and the *Hetubindu* we are still forced to rely on Tibetan translations, fragments and reconstructions. Research on Dharmakīrti has shifted from an earlier, more doxographic attitude towards an investigation of his work in context, focusing on the problems he was concerned with and the answers developed in his major works. An early attempt at interpretation by Stcherbatsky (1932) provided a fascinating overview, but was hampered by a too limited textual basis and a strong neo-Kantian bias in interpretation.

Dharmakīrti's first work, a treatise consisting of verses and partly explanatory, partly elaborative prose, is an audacious statement of his new logical theory, which he openly presents as a new interpretation of Dignāga's teaching, superior to that of his teacher Īśvarasena. This early work (called *Hetu prakaraṇa* by Frauwallner) is basically a study of the definition of logical reason (*hetu*) which may have been intended to supersede a similar work by Dignāga that is now lost (the *Hetumukha*), although it is not, in character, a commentary on Dignāga's treatise. It was incorporated by Dharmakīrti into the great verse-compendium of the *Pramāṇavārttika (Commentary on Valid Cognition)* as its first chapter ('On Inference'), and the parts in prose were regarded as Dharmakīrti's own commentary on this chapter. The other chapters of the *Pramāṇavārttika* are, in fact, conceived as a commentary on Dignāga's *Pramāṇasamuccaya (Collected Writings on Valid Cognition)*, the second chapter dealing with the proof of the Buddha's authority, the third with perception and the fourth with proof. Much is new in this work but, because it is structurally unbalanced, Dharmakīrti left it unfinished.

Drawing heavily on the earlier work, Dharmakīrti chose to compose a new statement of his ideas as an independent text in three chapters (on valid cognition and perception, on inference, and on proof), the *Pramāṇaviniścaya (Analytical Determination of Valid Cognition)*, of which the *Nyāyabindu (Drop of Logic)* is an abstract. Dharmakīrti returned to his first subject with the *Hetubindu (Drop of Logical Reason)*, treating it in a more formal way, with digressions devoted to the proof of momentariness, to a detailed presentation of his theory of causality, and to a final refutation of his teacher's attempt at developing an alternative logic in order to 'save' Dignāga's theory (see Momentariness, Buddhist doctrine of §§1, 5). In his last work, the *Vādanyāya (Rule for Disputations)*, he applied the results of his work on the logical reason to interpretations of the forms and rules governing public disputations, and refuted the canon of the Nyāya school that had seemingly been in use for that purpose up to his time (see Nyāya-Vaiśeṣika §6). In the context of Indian polemical practice, Dharmakīrti is unique in emphasizing that disputations have their purpose in the search for truth. Two small works, the *Sambandhaparīkṣā (Examination of Relations)* and the *Santānāntarasiddhi (Proof of Other Mental Continua)*, have not yet been attributed to a definite period of production.

2 Epistemology and logic

Except for the second and third chapters of the *Pramāṇavārttika* and the two small treatises just mentioned, Dharmakīrti's work is mainly concerned with developing Dignāga's epistemology and logic. He presents new ideas in the traditional way as the correct interpretation of the latter's thought. Epistemological thought, in this context, is an attempt at providing a rational frame for human practice, meaningful both in everyday life and in the pursuit of the ultimate goal indicated by the Buddha. In the second chapter of the *Pramāṇavārttika*, the Buddha is proven to be an authority on the value of all human activity and the final goals of spiritual aspiration. The third chapter, 'On Perception', is a critical analysis of the nature and possibility of perception. While elsewhere in his work, especially when dealing with epistemological issues, Dharmakīrti takes his stand on an ontology of 'critical realism' (the Sautrāntika tradition) and develops empirical models and categories for his theories, when analysing perception the option of a reality independent of cognition is dissolved, and an idealistic ontology (of the Yogācāra kind) remains (see Epistemology, Indian schools of §1; Buddhism, Yogācāra school of §§1-4).

Dharmakīrti's theory of meaning is nominalistic. Words and concepts refer only to the difference from others (*anyāpoha*) that is common to individual realities. This common character is unreal, but in human experience realities evoke a like judgment of their capacities, and thereby a link is provided between the false realm of beginningless constructs and the momentary instants of reality experienced (see Universals, Indian theories of §3).

Like Dignāga, Dharmakīrti accepts two kinds of valid cognition which hold good in practice: perception and inference. Perception is a cognition devoid of conceptual construction and is nonerroneous. Inferential cognition, being conceptual, is by nature erroneous, but if attained under the strict formal conditions of logic may be necessarily true. Verbal cognition based on authority or scripture is also inferential when it can be established as being trustworthy with regard to its specific, totally imperceptible object.

In the field of logic, Dharmakīrti transforms Dignāga's theory, which emphasized the formal aspects of logical reason, by insisting, like pre-Dignāga Sāõkhya logic, on the need for the necessary logical relation to have a foundation in reality. In fact, he interprets Dignāga's logic through his own, arguing that the former is not possible without implying the latter. The three marks of a logical reason required by Dignāga are fulfilled only by Dharmakīrti's three kinds of logical reason. Two possible connections in reality, real identity and causality, restrict the kinds of concepts from which others can be inferred to three: 'essential property' (*svabhāva*) and 'nonperception' (*anupalabdhi*), based on real identity, and 'effect' (*kārya*), based on causality. When these real connections are ascertained, inference is a valid cognition, although because it is conceptual by nature it is essentially problematic. However, when inference is correctly applied it may serve to remove or correct erroneous concepts and replace them with others more appropriate to reality (see Inference, Indian theories of §§5-6).

In Dharmakīrti's thought, logical theory and application are tightly interwoven. For example, he develops a new form of the proof of universal momentary destruction (*kṣaṇabhaõga*), deriving it, in the *Pramāṇaviniścaya*, from the concept of being (*sattva*). In elaborating this proof for the first time, he applies a new method for ascertaining the logical relation between the two concepts involved. Subsequently, in the later *Hetubindu*, this new method is also incorporated into the theory of logic.

Dialectical materialism

Dialectical materialism is the official name given to Marxist-Leninist philosophy by its proponents in the Soviet Union and their affiliates elsewhere. The term, never used by either Karl Marx or Friedrich Engels, was the invention of the Russian Marxist Georgii Plekhanov, who first used it in 1891. Engels, however, favourably contrasted 'materialist dialectics' with the 'idealist dialectics' of Hegel and the German idealist tradition, and the 'dialectical' outlook of Marxism with the 'mechanistic' or 'metaphysical' standpoint of other nineteenth-century materialists.

Dialectical materialism proclaims allegiance to the methods of empirical science and opposition to all forms of scepticism which deny that science can know the nature of reality. Dialectical materialists reject religious belief generally, denying the existence of non-material or supernatural entities (such as God or an immortal human soul). Unlike other forms of materialism, however, dialectical materialists maintain that the fundamental laws governing both matter and mind are dialectical *in the sense in which that term is used in the philosophy of G.W.F. Hegel.*

Although dialectical materialism is supposed to constitute the philosophical underpinnings of Marxism, Marx's only major contribution to it was his materialist conception of history. The more fundamental philosophical views of dialectical materialism have their main source in the writings of Engels, especially Anti-Dühring (1878), Dialectics of Nature (1875-82) and Ludwig Feuerbach and the End of Classical German Philosophy (1886). To this last work Engels appended the eleven 'Theses on Feuerbach' written by Marx in 1845, which contrasted the 'old' or 'contemplative' materialism with the practically oriented materialism which was to be the basis of the proletarian movement. Further developments of dialectical materialism are found in writings by V.I. Lenin and subsequent Soviet writers. Lenin's chief additions were his critique of 'empirio-criticism' (the empiricist phenomenalism of certain Russian followers of Ernst Mach, who argued that matter was to be reduced to sense data), and his conception of the 'partisanship' of all philosophical views.

1 Materialism

According to Engels, the fundamental question of all philosophy is 'Which is primary, matter or consciousness?' The question of 'primacy' is also put this way: 'Which, matter or consciousness, is the source of the other?' Materialism holds to the primacy of matter, idealism to the primacy of consciousness. Theism, which maintains that matter was created by a supernatural (divine) consciousness, is taken to be the chief form of idealism; under the title 'objective idealism' this is sometimes distinguished from 'subjective idealism,' the view that the material world exists only for the individual mind (see Idealism). Although these two versions of idealism do not appear to make consciousness the 'source' of matter in the same sense, it is even less clear in what way materialism takes matter to be the 'source' of consciousness. Dialectical materialists apparently mean to endorse whatever account of mind results from empirical scientific investigations; but they are confident that we already know enough to exclude supernaturalist, dualist or idealist accounts.

Dialectical materialists sometimes also give the 'primacy of matter over consciousness' an epistemological interpretation. Idealists are charged with a tendency to scepticism concerning knowledge of the material world, whereas materialists maintain that the material world is knowable through empirical science. This confidence is supported by appeal to the practical successes of empirical science, by which is meant both the results of experimentation (which involve the experimenter's practical interaction with the world) and the technological fruits of empirical science. Practice is asserted to be the sole criterion of truth; doubts and questions which cannot be given a practical significance are to be dismissed. The sceptical doubts of idealistic philosophy are held to be refutable in this way.

Dialectical materialists also insist that thought bears a certain determinate relation to matter, serving as its 'image' or 'reflection'. The world of consciousness is the material world 'translated into forms of thought'. The point of this last phrase seems to be that thought is given in certain determinate forms, which bear determinate relationships (especially developmental ones) to each other, whose subject matter is 'dialectics'. The epistemology of dialectical materialism opposes some traditional forms of empiricism in that it emphasizes the independent importance of determinate (dialectical) forms of thinking in the theoretical process through which science comes to know reality.

Engels, for example, argues that Marx's theory of capitalism is 'dialectical' by emphasizing structural parallels between Hegel's *Science of Logic* and Marx's *Capital*.

2 Dialectics

If the opposition of idealism and materialism concerns the fundamental question of philosophy, the opposition between metaphysics and dialectics concerns the fundamental issue of method. The 'metaphysical' method (as Engels calls it, borrowing the term from Hegel's critique of pre-Kantian philosophy) is identified with the mechanistic programme of early modern science, which is taken to have been discredited by such nineteenth-century discoveries as electromagnetic field theory. But following Engels, dialectical materialism upholds (at least a modified version of) the critique of early modern science presented by German idealism and its 'philosophy of nature', which opposes formalism and reductionism and emphasizes phenomena of organic interconnection and qualitative emergence. Early modern mechanism was a form of atomistic reductionism, which takes the world to consist fundamentally of material corpuscles interacting and combining in various ways according to unchanging laws. Essences or natural kinds no longer have any fundamental role to play in science, since all qualitative differences are ultimately to be reduced to quantitative differences at the fundamental level of explanation.

This picture was rejected by German idealists such as Schelling and Hegel. Under the title 'philosophy of nature' (*Naturphilosophie*) they attempted to develop a comprehensive picture of nature as the expression of an absolute reality transcending nature. Although Engels could not accept the anti-naturalist form of idealist philosophy of nature, he shared many of its aims and wanted to vindicate its 'dialectical' principles against contemporary materialists such as Ludwig Büchner and Erich Haeckel, whom he regarded as still fettered by the old mechanism or 'metaphysics'. From the idealists, Engels retained the idea that the natural world involves forms of organization that are essentially different in quality, each with its own distinctive regularities; they are irreducible to any fundamental form of matter or unchanging set of laws. Engels' new materialism holds that new essences or forms of organization may emerge in the course of history. Thus the commonest charges dialectical materialists bring against metaphysical materialism are that it ignores the fundamentally developmental nature of matter, that it tries to reduce all change to quantitative change, and that it fails to recognize internal contradictions in the nature of material things as the fundamental source of change. The antidote is to recognize and employ the dialectical laws of thought.

3 Dialectical laws

First law: the unity of opposites. The nature of everything involves internal opposition or contradiction. This is probably the most obscure dialectical idea, because it is the most wilfully paradoxical, seeming at times to amount to a flat denial of the logical law of non-contradiction. Echoing Hegel's 'resolution' of Zeno's paradoxes, for example, Engels writes: 'Motion itself is a contradiction… coming about through a body at one and the same moment of time being both in one place and in another place, being at one and the same place and also not in it'. Regarded as an attempted solution to Zeno's paradoxes, such remarks are at best extremely obscure; they do apparently intend to challenge the canonical status of traditional logic, and put in question even the law of non-contradiction.

Hegel, however, sometimes draws a distinction between the way the principles of traditional logic as they are 'meant' (so understood, he regards them as trivially true and of no philosophical interest) and a deeper 'metaphysical' significance that may be discovered in them (see Hegel, G.W.F. §6). Understood in the latter way the laws are false, but importantly so, because they represent the standpoint of the abstract 'understanding' which fails to comprehend the essential interrelatedness of things and their necessary development. Understood as a denial of traditional logic on this metaphysical interpretation, the law of the unity (or interpenetration) of opposites claims something which, if not always entirely clear, is at least plainly not (in the traditional sense) logically self-contradictory: namely, that the essences of things include differing and opposed, often complementary, elements or processes, and that essential change or development in the world occurs through the conflict of these opposed moments. It is not hard to see how an emphasis on the organic could give rise to such a view, since the life of an organism often consists in a dynamic equilibrium of opposed processes (Engels' example is nutrition and excretion). Further, it is not difficult to see how a representation of changes in the world as resulting from conflicting local tendencies deemed essential to a certain organization constitutes a clear alternative to a reductive

mechanistic explanation in terms of unchanging basic elements following general laws. Some later dialectical materialists distinguish 'non-antagonistic' contradictions from 'antagonistic' ones: that is, opposed processes that harmonize and reinforce one another from those which tend towards the essential destruction of the complex they constitute. They also distinguish 'internal' contradictions from 'external' ones, the former constituting the essential nature of a phenomenon and the latter involving the contingent collision of things with different natures.

Second law: quantity and quality. Quantitative change always eventually leads to qualitative change or development. Engels cites such phenomena as the suddenness of the transition between the solid, liquid and gaseous states of substances as their temperatures change. The important thing in such examples is that purely quantitative changes lead to the emergence of new qualities which cannot be adequately grasped in terms of the concepts in which the purely quantitative changes can be formulated. Once again, the rejection of mechanistic reductionism is evident both in the insistence on the existence and importance of qualitative differences and in the idea that what is ultimately important, even about the quantitative changes studied by the mechanists, is the way they lead to qualitative differences.

Third law: negation of the negation. Change negates what is changed, and the result is in turn negated, but this second negation leads to a further development and not a return to that with which we began. Marx, in Volume 1 of *Capital* (1865), famously described capitalist property as the 'negation' of individual property based on the labour of the proprietor, and communist property as the 'negation' of capitalist property, hence as the 'negation of the negation'. The point once again is to emphasize the emergence of what is qualitatively new, and the fact that this emergence is to be understood in terms of the specific essence of that which is in process rather than in terms of general laws applying to simple elements of which it is composed.

The three dialectical laws are often seen to operate in close association, as when 'negation' is the result of antagonistic or 'contradictory' tendencies essential to something, which thereby change it into something qualitatively different. In general, dialectical thinking tries to explain change as the outcome of conflicts which emerge from the essence of something, which are resolved when its essence is transformed and it attains a new stage of its development. This last idea is sometimes presented by popular expositors of 'dialectics' in the jargon of 'thesis-antithesis-synthesis'. This particular bit of grotesque jargon, however, is almost never found in the writings of dialectical materialists themselves. It was never used by Hegel or Engels, and was used by Marx only once, solely for the purpose of ridicule. Its employment nearly always betrays either ignorance of dialectical thinking or contemptuous hostility to it - usually both these at once.

4 Historical materialism

The most prominent application of dialectical materialism is to the historical development of society, in the shape of Marx's 'materialist conception of history'. It has sometimes been made a matter of controversy how far Marx's economic theory of the history of capitalism and his shrewd analyses of contemporary political events actually embody his theoretical programme, the main lines of which are stated in the *German Ideology* (1845) and the Preface to *Toward a Critique of Political Economy* (1859). The fundamental thing in human history is the productive powers of society and their tendency to grow. Productive powers at a given stage of development determine the nature of human labouring activity because labour consists in the exercise of precisely those powers. A given set of productive powers also thereby favours certain 'material relations of production', forms of human cooperation or division of labour, which are not directly part of them, but facilitate their employment to a greater degree than rival forms would do. They thereby also favour certain 'social relations of production', systems of social roles relating to the control of the production process and the disposition of its fruits. It is this system of social relations of production which Marx calls the 'economic structure of society' which forms the 'real basis' of social life on the materialist theory, conditioning 'superstructures' such as the political state and the 'ideological' forms of consciousness found in religion, philosophy, morality and art.

Within the framework of any system of social relations of production, society's productive powers expand at a greater or lesser rate, depending on the historical circumstances, including the social relations themselves. Eventually, however, a given set of social relations of production are outgrown or rendered obsolete by the productive powers. The prevailing relations either make it difficult to employ the existing powers or else fetter the further development of these powers. Powers and relations of production thus come into conflict or 'contradiction'; an 'epoch of social revolution' begins. The outcome of the conflict is the transformation of the

relations of production to bring them into line with the productive powers so as to facilitate the further expansion of these powers. Changes in the superstructure of society, including its political and legal institutions, are to be explained by the required changes in the social relations of production. The mechanism by which these adjustments are to be carried out is the class struggle. At a given stage of history, that class is victorious whose class interests consist in the establishment of that set of production relations which best suits the productive powers at that stage.

Historical materialism exemplifies the principles of dialectical materialism: each mode of production has its own essential laws and tendencies; each has inherent tendencies to undermine itself and change into something new, and these tendencies operate through oppositions or contradictions essential to it. Although Marx occasionally applies it to pre-modern societies, this theory of history was obviously suggested to him by the rise of capitalism; Marx envisages the overthrow of capitalism and the rise of socialism as following the same pattern of historical development.

5 Materialism and practice

Beginning with Marx's 'Theses on Feuerbach' (1845), one prominent claim made by dialectical materialists is that their view alone provides for an adequate relation of philosophy to 'practice'. In the 'Theses', Marx meant to side with Hegelian philosophy against the empiricism of Feuerbach and eighteenth-century mechanistic materialism, holding that its conception of our relation to nature is exclusively contemplative, while until now only idealism has grasped the 'active side' of this relation (albeit inadequately). An adequate grasp of practice, in his view, is based on the understanding of philosophy's involvement in the fundamental social struggles brought to light by historical materialism. Only in this way do we become fully conscious of ourselves as natural, and naturally historical, beings.

Lenin's theory of 'partisanship' was an attempt to develop this important side of Marxism: the recognition that all philosophical thinking must be understood in its social significance and its relation to historical struggles. The 'partisanship' of philosophy is all too easy for us to stigmatize as simply an excuse for constraining philosophical thought through party dogma. But the philosophical import of the doctrine (as distinct from its political abuses) is rather to liberate thinking by making it more self-aware as regards its class basis and social situatedness (see Lenin, V.).

6 The fate of dialectical materialism

The plausibility of any theory as programmatic as dialectical materialism must finally depend on how fruitful it is in its actual employment. As the official philosophy of Soviet Marxism-Leninism, however, dialectical materialism was doomed to stasis and sterility by the repressive and authoritarian political conditions under which its practitioners were forced to operate. Thus a philosophy whose spirit was to challenge traditional religious authority and to exalt the fact of qualitative novelty and ceaseless progressive development has become our century's most notorious example of ossified dogmatism, incapable either of internal development or of response to external change, often degenerating into the mechanical repetition of empty phrases borrowed from the science and philosophy of an earlier century. Yet this historical irony too easily obscures the important fact that the basic aims and principles of dialectical materialism are very much in harmony with any outlook which perceives a fundamental opposition between scientific theories and religious myths, tries to address the scientific challenges posed by the failure of the seventeenth and eighteenth century mechanistic programme, and seeks a scientific metaphysics as the basis for an enlightened view of the world.

Dialectical school

An offshoot of the Megarian school, and active c.*350-250* BC*, the Dialectical school was an important precursor of Stoic logic. Its leading members were Diodorus Cronus and Philo. Its interests included modality, conditionals and logical puzzles. Its primary allegiance was probably Socratic, but with some additional debt to the Eleatic Zeno.*

The Dialecticians have regularly been assumed to be identical with the Megarians (see Megarian school), but several testimonies show them to be a distinct and rival school. The Megarians are even reported to have filched pupils from them (Diogenes Laertius, II 113). Although linked by a common interest in sophisms, by a shared Socratic background tinged with Eleaticism and by the fact that Clinomachus of Thurii, official founder of the Dialectical school, had been a pupil of the Megarian founder Euclides, the two schools exhibited largely different philosophical outlooks. Where the Megarians emphasized and developed Socrates' specifically moral teachings, the Dialecticians seem to have stressed the intrinsic value of dialectical activity - argument by question and answer. Since Socrates himself had called dialectical discussion the greatest human good (Plato, *Apology* 38a), the school's stance can be seen as a bid for Socrates' mantle, in direct competition with the Megarians and other Socratic schools (see Socratic schools). The school's appearance in a list of 'ethical' sects (Diogenes Laertius, I 18) can therefore be taken seriously. If Diodorus, in devising his own four arguments against motion, was also indicating allegiance to Zeno of Elea, the acknowledged founder of dialectic, the move was perhaps legitimized by Plato's *Parmenides*, where the young Socrates welcomes a lesson in Zenonian dialectic. What united the school was its commitment to dialectical virtuosity as such. On individual points of logical theory they differed widely.

Clinomachus is reported as 'the first author of treatises on propositions, predicates etc.' (Diogenes Laertius, II 112). The school's pioneering work on the nature of predicates is confirmed by Seneca (*Letters* 117.12), but it is also clear from Diodorus' and Philo's work on conditionals and modal logic that they anticipated the Stoics, and differed from Aristotle, in treating entire propositions rather than terms as the basic units in logic on this and on Diodorus' other work, see Diodorus Cronus and Philo the Dialectician). Their theory of sign inference also paved the way for Stoicism, as did their analysis of inferential validity if, as Ebert (1991) has argued, a number of references to 'the dialecticians' in Sextus Empiricus are to this school. Zeno of Citium, founder of Stoicism, studied under Diodorus.

Diodorus' Master Argument, defending his definition of 'possible' as 'what is or will be true', was their most celebrated product. A less known companion piece, also attributed to the school, is the Mowing Argument, which tries to devalue the word 'perhaps' by arguing that every prediction must be either simply true or simply false. Although both arguments lent themselves to deterministic interpretations, the different modal views of Philo and the little-known Panthoides did not, and the school as such clearly had no commitment to determinism.

Another area of dialectical activity, with strong Socratic antecedents, was the framing of definitions. A Dialectical definition of 'expertise' (*technē*) is recorded, and Aristotle (*Topics* VI 10) criticizes that of 'life' by the early Dialectician Dionysius of Chalcedon.

Dialogical logic

Dialogical logic characterizes logical constants (such as 'and', 'or', 'for all') by their use in a critical dialogue between two parties: a proponent who has asserted a thesis and an opponent who challenges it. For each logical constant, a rule specifies how to challenge a statement that displays the corresponding logical form, and how to respond to such a challenge. These rules are incorporated into systems of regimented dialogue that are games in the game-theoretical sense. Dialogical concepts of logical consequence can then be based upon the concept of a winning strategy in a (formal) dialogue game: B is a logical consequence of A if and only if there is a winning strategy for the proponent of B against any opponent who is willing to concede A. But it should be stressed that there are several plausible (and non-equivalent) ways to draw up the rules.

1 Main characteristics

Logic is to provide us with viable concepts of logical consequence, logical truth, consistency and so on, and to that end to elucidate the meaning of logical constants (see Logical constants). Dialogical logic, which is the logical part of dialogue theory, goes about this by assigning to each logical constant a clear 'meaning-in-use', where the context of use is one of critical dialogue arising from a conflict of opinions about a statement: the initial thesis. This thesis - the question at issue, one might say - is challenged by the opponent (*O*) and defended by the proponent (*P*). The opponent may or may not have granted some statements in advance: the initial concessions or hypotheses of the dialogue. The dialogical approach is to be compared to, and contrasted with, semantic or model-theoretic characterizations of the logical constants (see Model theory) and deduction-theoretic characterizations (see Proof theory; Natural deduction, tableau and sequent systems).

Each logical constant is characterized by the specific modes of challenge of which the participants may avail themselves to attack or question a statement with that particular logical constant as its principal operator; as well as by the specific responses to these challenges. For instance, a conjunctive statement '*A* and *B*' can be challenged in two ways: by questioning *A* and by questioning *B*. The response to the first type of challenge consists of *A*, whereas the response to the second type of challenge consists of *B*. In the case of a disjunctive statement '*A* or *B*', however, the only type of challenge pertains to this statement in its totality, but the responses are the same, with the distinctive difference that in this case the choice between *A* and *B* is the respondent's, rather than the challenger's. A survey of these so-called logical rules is given in the table.

The logical rules are not sufficient, for the meaning of each logical constant also depends on global characteristics of the dialogues. Structural rules stipulate who may challenge what and how often, whether responses may be repeated, and so on. Finally, rules for winning and losing determine the situations in which a participant may be declared to be the winner (or loser) of the dialogue. A full set of rules of all three types (see the table and lists of rules below) defines a 'dialogue game', or 'dialectic system'.

If a dialogue game makes use of an interpreted nonlogical vocabulary, the game and its dialogues are called material; otherwise they are called formal. In material games, typically, elementary statements can be defended by pointing out their (extra-dialogical) truth. Thus observation and other ways of fact-finding are connected with material dialogues. In formal dialogue games these material modes of defence are not available.

2 An example

The following formal dialogue game yields intuitionistic (constructive, effective) predicate logic (see Intuitionism). It is based on a first-order language for predicate logic with an infinity of individual constants *a*, *b*,…. Formulas are denoted as *A*, *B*,…. The result of substituting an individual constant *a* for the free variable *x* in the formula *A* is denoted as $A[a/x]$.

This game is asymmetric in the following sense: at all times *P* has a statement to defend, whereas *O* never has a thesis to defend. However, *P* must have some means to exploit the initial concessions. To that end *P* is allowed to question the concessions in order to generate more detailed concessions. The corresponding moves of question (by *P*) and answer (by *O*) are formally identical to the moves of challenge (properly so called) by *O* and response (or, defence) by *P*, but the intuitive motivation is different. Thus the asymmetry of the game remains hidden as far as the logical rules are concerned. It is clearly borne out, however, by the structural rules and by the very different

ways *P* and *O* can win a dialogue.

Logical Rules

	Statement by proponent	**Challenge/question by opponent**	**Defence/answer by proponent**
Rule $_{\rightarrow}$	$A \rightarrow B$	A	B
Rule $_{\neg}$	$\neg A$	A	$\perp$ (elementary statement of absurdity)
Rule $_{\vee}$	$A \vee B$	?	A or B (proponent chooses)
Rule $_{\wedge}$	$A \wedge B$	A?	A
		or B? (opponent chooses)	B
Rule $_{\forall}$	$\forall x A$	a? (opponent selects a constant)	$A[a/x]$
Rule $_{\exists}$	$\exists x A$	?	$A[a/x]$ (proponent selects a constant)
Rule $_{\mathrm{El}}$	elementary statement	?	none

Structural Rules

1 There are two participants: the proponent, *P*, who defends a thesis, and the opponent, *O*, who may or may not have granted a number of concessions.
2 The participants move alternately. *O* makes the first move: a challenge of the thesis.
3 Each move by *O* is a challenge or an answer according to a logical rule.
4 Each move by *P* is a question or a defence according to a logical rule, or a winning remark, that is, either '*Ipse dixisti!*' ('You said so yourself!') or '*Absurdum dixisti!*' ('You said something absurd!').
5 *P* is not allowed to question *O*'s elementary statements.
6 A winning remark '*Ipse dixisti!*' is allowed only if the most recently challenged statement of *P*'s can also be found among *O*'s concessions.
7 A winning remark '*Absurdum dixisti!*' is allowed only if $\perp$ can be found among *O*'s concessions.
8 The only statement *P* is allowed to defend is the one that was most recently attacked by *O*.
9 Except for the initial challenge, each move by *O* is to consist of a reaction to the immediately preceding move by *P* (answering *P*'s question, or challenging a newly introduced statement).
10 Before the onset of the dialogue proper, *P* is to announce a limit on the number of *P*-moves. *P* is not allowed any moves beyond that number.

Rules for Winning and Losing

1 *P* wins by making a winning remark.
2 *O* wins whenever it is *P*'s turn to make a move but no legal move is available.

3 Motivations and applications

The connection between dialogues and logic, which goes back to Aristotle's *Topics*, was reintroduced by Paul Lorenzen in 1958 (see Lorenzen and Lorenz 1978). Originally, the motivation was to be found in the philosophy of mathematics: the dialogues were to yield a criterion of constructivity and to justify a constructive logic without

recourse to Brouwerian solipsism (see Intuitionism). But studies by Kuno Lorenz and others were not slow to point out that with a little fiddling of the structural rules the dialogue games could be forced to yield classical logic instead, although constructive logic seemed more 'natural' from the dialogical point of view.

In the meantime it had become clear how logical concepts were to be defined dialogically. We have seen above how a definition of logical consequence can be framed in terms of the existence of a winning strategy for the proponent in a formal game. The case of an empty set of concessions gives us a definition of logical truth. Consistency of a set of statements can be defined as the existence of a winning strategy for an opponent who concedes these statements against a proponent who defends $\perp$. This strategy shows how *O* can maintain this position without conceding absurdity. Clearly, different formal dialogue games may give rise to different concepts of logical consequence; to different logics, one might say.

The challenges and responses given in the logical rules of dialogical logic are closely similar and often identical to those given in Hintikka's rules for game-theoretic semantics (see Semantics, game-theoretic). But in game-theoretic semantics one tries to exploit the concept of a game to construct a semantic theory (for natural language), whereas dialogical logic is rather to be conceived as providing an alternative to the semantic approach. Even so, the two approaches are closely related.

Later on dialogical logic came to be part of a programme for a normative reconstruction of the language of science, ethics, philosophy and politics that was worked out by Paul Lorenzen and others see Lorenzen and Schwemmer 1973) in the so-called Erlangen school of German constructivism (see Lorenzen, P.). The dialogue rules contribute to this programme by giving us reconstructed versions of the logical constants.

More generally, dialogical logic has been influential in the development of argumentation theory, including the theory of argumentative discussions and fallacy theory.

Dicey, Albert Venn (1835-1922)

A.V. Dicey, who held the Vinerian Chair of English Law at Oxford University between 1882 and 1909, is widely regarded as the high priest of orthodox constitutional thought in Britain. Living through a period of great political and economic change, Dicey recognized that the duty of the constitutional lawyer could no longer be one of simply venerating Britain's ancestral, unwritten constitution. He appreciated the need to try to lay bare its legal foundations and to identify its fundamental principles. In embarking on this exercise, Dicey, a follower of John Austin, employed an analytical method which treated law as a datum to be analysed and classified and which served to furnish a descriptive account of how law's various divisions fit together to provide an ordered whole. Dicey was the first to apply this legal positivist method to the study of constitutional law in Britain. The method became so ensconced in legal thought in twentieth-century Britain that today lawyers scarcely acknowledge any work in constitutional law which predates Dicey's work. It is as though he invented the subject.

In his classic text, *The Law of the Constitution* (1885), Dicey defined the subject of constitutional law as the study of the rules which affect the distribution or the exercise of the sovereign power of the state. These rules comprise two sets: laws in the strict sense which are enforced by courts; and conventions, understandings, habits and practices which are not so enforced but which regulate the conduct of the members of the sovereign power. Through this formalistic and positivistic distinction between law and convention, Dicey was able authoritatively to demarcate the boundaries of the subject.

Dicey's influence, however, has not been confined to his method. His view of the character of constitutional law was shaped by a particular political outlook which, on the face of it, seemed far removed from an Austinian method. This outlook was a form of 'diffused Burkeanism' (see Burke, E.) which was a characteristic of much of nineteenth-century English political thought. He believed that the English system - resting on a love of order, a Conservative spirit, and a belief in ordinary morality as a guide to public life - represented the climax of political achievement. These qualities were to be found, above all, in the common law heritage and, owing to the fact that it is a judge-made constitution, within the British constitution itself.

In *The Law of the Constitution* Dicey identified three guiding principles underpinning the British constitution: the legislative sovereignty of the Queen-in-Parliament; the universal rule throughout the constitution of ordinary law (otherwise understood as the rule of law); and the ultimate dependence of constitutional conventions on the law of the constitution. His objective was to show how, once their interlocking nature is understood, these principles were conducive to the promotion of liberty. Parliamentary sovereignty, the right of Parliament to make or unmake any law whatsoever, was the dominant characteristic of the political institutions. Though an instrument well adapted for the establishment of democratic despotism, Dicey argued that the sovereignty of Parliament, as contrasted with other forms of sovereign power, favoured the supremacy of law: first, because the constituent parts of Parliament provided checks and balances (the idea of 'self-correcting democracy'); and, second, because the rule of law implies the predominance of rigid legality throughout institutions and thus increases the authority of Parliamentary sovereignty (see Sovereignty §§2-3).

Dicey's formulation of the idea of the rule of law has been viewed as the most influential restatement of the principle since the eighteenth century. Nevertheless, it is not without its ambiguities. Dicey suggested that the concept had three meanings: the absolute supremacy of regular law as opposed to the influence of arbitrary power; the principle of equality before the law; and, finally, that the constitution is a product of ordinary law and thus that constitutional law is not the source but the consequence of individual rights. Running throughout these meanings, there lies a relatively specific conception of law as a universal body of general rules which have evolved through time and which are enunciated by judges. Also implicit within, but fundamental to, the conceptual structure of Dicey's constitutional thought is the idea of the separation of powers. Dicey's view that Parliamentary sovereignty favours the supremacy of law seems to hold sway only in so far as we regard the legislative function as that of laying down general rules for society rather than incorporating the vesting of discretionary powers in executive agencies. Similarly, Dicey's notorious view that administrative law undermined the rule of law can readily be understood once administrative law is viewed as an infringement of the principle of the separation of judicial and executive powers (see Rule of law (Rechtsstaat) §§1-2).

The Law of the Constitution, though masquerading as an introductory treatise of positivist legal science, is in reality a work of considerable intellectual imperialism. The Whig interpretation of history which underpins it was later laid bare in *Law and Opinion in England during the Nineteenth Century* (1905), a work much criticized by historians and which in actuality simply explicates Dicey's intellectual and political assumptions. These assumptions, however, did not survive Dicey's own times. In 1914 he wrote a long introduction to the eighth edition of *The Law of the Constitution*. Taking the form of a lament, it mourned a loss of faith in Parliamentary government and a decline in veneration for the rule of law which Dicey believed had occurred since the mid-Victorian era and which he suggested were threatening the principles of the British constitution which he had first sought to formulate in 1885. However, Dicey's actual concerns mattered little. By this stage, the historical figure had more or less disappeared, to be replaced by an entity known as 'Dicey' which has lived on through successive generations of lawyers as the expositor of the fundamental principles on which the British constitution is founded.

Diderot, Denis (1713-84)

Chief editor of the great eighteenth-century Encyclopédie *(1751-72), Diderot set out a philosophy of the arts and sciences which took the progress of civilization to be a measure of mankind's moral improvement. He did not regard that progress as having produced universal benefits, however, and perceived the Christian religion which had accompanied it as morally harmful to those who subscribed to it and even more dangerous to societies thus far untouched by it. Religious dogmas tended to pervert the organic development of human passions, and secular education which presumed that all minds were equally receptive to instruction threatened to thwart the natural evolution of human faculties in other ways.*

Like Rousseau, Diderot subscribed to a philosophy of education which encouraged curiosity rather than promoted truth. He stressed the need for the adaptability of moral rules to the physiological characteristics of the individuals to whom they applied, pointing to a connection between human cultures and biology in a manner that would influence fresh outlooks upon the sciences of man at the end of the Age of Enlightenment.

1 Encyclopedic polymath

One of the most central figures of the European Enlightenment, Diderot was chiefly renowned in his own lifetime as the principal editor of the *Encyclopédie* (1751-72), constructed as a monument of human reason and invention, like the Crystal Palace that would be built in London a century later in celebration of an age of industry and commerce. More than any other philosopher of the eighteenth century, he shaped his intellectual career around the production and circulation of books, which in progressive circles were held to be both the vehicle and measure of enlightenment for an epoch of greater literacy and prosperity than Europe had ever known before.

Appointed with Jean Le Rond D'Alembert as joint editor of the *Encyclopédie* in 1747, Diderot initially undertook to write more articles himself than any other contributor to this reasoned dictionary of the arts and sciences, whose publishing history from 1751 would eventually extend over a period of thirty years, and whose thirty-five volumes would come to embrace 20 million words and more than 2,000 plates. As the guiding spirit of that collective enterprise of men of letters, Diderot often reassembled the ideas of other thinkers, drawing upon ancient and modern sources alike, from Lucretius to Shaftesbury. Having begun his literary career around 1743 as a translator, he proved the Enlightenment's most expert literary ventriloquist, sometimes passing off borrowed material as if he had written it himself, sometimes ascribing his own ideas to others.

In part because so much of his best work was to appear posthumously, often in the form of fictional dialogues, Diderot came to be regarded as the Enlightenment's most eclectic thinker, displaying a special fondness for the pluralist dimensions of eclecticism in general in his own entry on that very subject for the *Encyclopédie*, itself indebted to other authors. In *Le Neveu de Rameau (Rameau's Nephew)* (1762-74) in particular, deemed by Hegel, Goethe and Marx to be the finest work of the whole Enlightenment, he portrays the character of the most explosively original and romantic personality of eighteenth-century European literature as at odds with itself and also with Diderot, who figures both as the author of the dialogue and a personage within it, depicted as conventional in upholding a bourgeois code of morals. As distinct from some of his equally celebrated contemporaries - such as Montesquieu, Voltaire or Rousseau - Diderot elaborated no single overriding doctrine, nor did he devote himself to one great intellectual crusade.

Especially well versed in the history of philosophy, he extolled its ancient and modern achievements alike, from Epicurean doctrines of continual flux, to Spinozistic conceptions of selfsufficiency, to the atheistic materialism of La Mettrie and Maupertuis. In his *Pensées philosophiques (Philosophical Thoughts)* of 1746, largely inspired by Shaftesbury, he put forward a set of aphorisms that expressed notions of natural law and ideals of natural religion, which could be engraved in the human heart without need of Christian scruples. In his *Lettre sur les aveugles (Letter on the Blind)* of 1749, he set out a case for the adaptability of the senses as evidenced by the fact that mental images could be formed without sight or conversations pursued without sound, believing that powers of perception were transitive across human faculties and did not themselves spring from sensory experience. The late eighteenth-century teaching of sign languages to the deaf, and the deep structural grammars of modern Chomskian linguistics, were to draw inspiration from such claims that fundamental human capacities are not determined by the contingencies of their exercise. At the time of its publication, however, Diderot's *Lettre sur les aveugles* only

managed to invite the suspicion that he was a materialist and atheist, on which grounds he was to be imprisoned in Vincennes for over three months.

In the longest of the contributions to the work of which he was chief editor, the article '*encylopédie*' itself, he expounded themes of practical or applied philosophy that could bring the arts and sciences of civilization together, by encouraging the interpenetration of the liberal with the mechanical arts and the cooperation of specialists across disciplines, along lines that bridged what we have come to term 'the two cultures'. In showing how science had been rendered useful to the public interest or common good through such inventions as the compass and the printing press, Diderot sought to provide tangible illustrations of a Platonic ideal of promoting virtue through knowledge. His goal, like that of so many other *philosophes* of the eighteenth century, was to cast off the veil of ignorance and lift the yoke of precedence, thus overcoming dead dogma. Almost as much as D'Alembert's preliminary discourse to the *Encyclopédie*, Diderot's own article on that very subject could be read as a general manifesto of the Enlightenment.

2 Speculating about politics

His political philosophy was first propounded in the *Encyclopédie*, particularly in articles such as *autorité politique*, which offers a theory of the social compact that binds both the prince and his subjects to one another without recourse to theological sanctions; and *droit naturel* (natural law), which sets out a theory of universal justice with respect to mankind's 'general will', a term of scant significance in the history of political thought before Diderot gave it fresh impetus. In 1774, in his *Observations sur le Nakaz*, or commentary on a new code of law for Russia as proposed by the empress Catherine the Great, he called for a programme of secular education to stimulate the civilization and selfreliance of that country through indigenous and small-scale enterprises, opposing the importation of Western physiocratic doctrines and their schemes of wholesale agrarian reform within a cultural environment to which they were ill-suited. Catherine had purchased Diderot's library and had invited him to St Petersburg, but she failed to convince him of the wisdom of her efforts to reform the political system of her nation along lines she imagined had already been achieved in the West. While advocating the emancipation of serfs, which was not to her liking, Diderot was convinced that material progress in Russia should proceed apace with its intellectual development rather than in accordance with alien precepts of modernity.

As editorial spokesman for the cause of enlightenment and a major contributor on political subjects to the *Encyclopédie*, Diderot stood for principles which appear to differ sharply from those of Rousseau, for fifteen years his closest companion, who had conceived the central idea of his own philosophy of history - which forms a moral critique of the progress of the arts and sciences - en route to visit his friend in prison. Whereas Rousseau decried the moral consequences of the progress of the arts and sciences, Diderot applauded them. Whereas Rousseau subscribed to ideals of spartan republicanism, Diderot was cosmopolitan and willing to encourage monarchical regimes so long as their authority was tolerant and benign, directed to the promotion of the public interest. Rousseau's notion of the general will, as an ideal of public engagement only conceivable to the citizens of selfgoverning states, was largely designed to contradict Diderot's conception of the same term as pertaining to the common humanity of individuals even when motivated by self-interest, in so far our notions of what is right and good do not, Diderot supposed, depend upon our political identities.

If, for Rousseau, men's morals were shaped by their politics, Diderot was instead convinced that politics were fundamentally shaped by morality. In his article *hobbisme* for the *Encyclopédie*, he contrasted Rousseau's idea that society rendered mankind malicious with a Hobbesian notion that war was our species' natural state, rejecting them both (see Hobbes, T.). Believing that conflict was not inescapable either in nature or in society, he upheld an alternative doctrine, which he drew ultimately from Pufendorf's *De iure naturae et gentium* (1672), that human frailties had rendered civil society necessary, while the natural sociability of selfishly motivated persons had rendered it possible and, at least in principle, beneficial as well (see Pufendorf, S.).

3 On primitivism, religion and sexuality

In his *Supplément au Voyage de Bougainville (Supplement to the Bougainville Journey)*, dating from the early 1770s but largely unpublished until after his death, Diderot was to portray the virtues of a primitive society in colours so attractive as to seem to shed doubt upon his allegiance to the moral splendours of civilization. This text, purporting to serve as an appendix to one of the earliest descriptions of Tahiti, contrasts an exotic world

characterized by the zealous satisfaction of bodily appetites with a familiar world wherein it is dictated that they should be repressed. Diderot's depiction of a society in which sexuality is celebrated, and within which incest, adultery and fornication are not held to be either criminal or sinful, forms a critique of monogamy, celibacy and sexual repression in the West at the same time as it offers tribute to the promiscuity of Polynesians.

The *Supplément*'s fictional opposition of two cultures - one stirred naturally by libidinous desire, the other artificially held in check by religion and hypocrisy - owes a debt to the *Lettres persanes (The Persian Letters)* (1721) of Montesquieu and more generally to eighteenth-century travellers' tales, either real or imaginary, which found European, and most particularly Christian, civilization to be at fault in the light of Oriental alternatives. In granting tangible presence and geographical specificity in the modern world to a population that still enjoyed the freedom of its state of nature, Diderot also seems to have drawn inspiration from Rousseau's *Discours sur l'inégalité (Discourse on the Origin of Inequality)* (1755). Like Rousseau, he judged that the moral values which prevailed in the West were often contrary to human nature, which they distorted through artifice, subterfuge and selfdeception.

Especially with respect to the sexual longings of individuals in Christian communities, and above all the warped personalities of their monastic priests, Diderot was convinced that in Western cultures there had arisen a great gulf between human physicality and morality. But he did not share Rousseau's view that such a gulf was unbridgeable. He imagined that Tahitian society showed how it could be overcome, in promoting the public interest out of individuals' sexual proclivities, thereby stimulating a socially welcome growth in population. The irreverent, sensuous, liberal, anti-colonial and utilitarian themes of the *Supplément au Voyage de Bougainville* pursue, in different idioms, a philosophy which springs from the same point of view that informed Diderot's contributions to the *Encyclopédie* and to which he was to subscribe virtually all his life - the belief that great public benefits may spring from unconstrained selfish sociability. In holding to such a doctrine, more often associated in diverse formulations with Bernard Mandeville and Adam Smith, Diderot espoused one of the most central moral philosophies of the whole Enlightenment.

4 Theory of education

At least some of the tensions which are manifest in his writings reflect the clash of principles and personalities that he perceived in the world at large. At once a materialist and an atheist, Diderot was determined to describe the behaviour of individuals empirically, in all their diverse, contrasting and irregular forms. Such diversity and contrast were features of human nature as much as of human history, he supposed and, in his *Réfutation de l'ouvrage d'Helvétius intitulé 'L'Homme' (Refutation of Helvétius' Work Man)* of 1774, he accordingly took issue with the famous dictum of Helvétius' *De l'homme*, published posthumously in 1773, that 'l'éducation peut tout' (see Helvétius, C.-A.). The proposition that education can achieve everything was false, according to Diderot, because it presumed that men and women were everywhere identical and that differences in character depended entirely upon the circumstances of a person's upbringing.

Because this supposition appealed to a notion of human equality, it was tempting to believe, in the light of it, that all individuals at birth shared the same capacities. But that was a delusion, Diderot contended, based on the false premise that each person was motivated only by his or her sensations which, through instruction and refinement, would become the grounds of every sort of rational and moral judgment. It was impossible, Diderot insisted, to pass directly from sensation to judgment or, in effect, from animal reflexes to human design. Intraspecifically, it had to be noted that only humans possess the capacity to reason and thus to formulate ideas and combine them into judgments. Interspecifically, it was necessary to remark that individuals exhibit their reason in different degrees, mental capacity as a whole being unequally distributed. In allowing with Helvétius that vices do not spring from human nature but are generally attributable to harmful social practices and teachings, there should be no presumption that all individuals have good minds, endowed with a latent natural genius just awaiting cultivation and training.

Diderot's critique of the philosophy of education of Helvétius bears a striking resemblance to Rousseau's challenge, made in *Émile* a decade earlier, of much the same theory of the formation of the human intellect and character already sketched in Helvétius' *De l'esprit* (1758). Rousseau and Diderot were each convinced that genius cannot be instilled by tuition and that education ought to nourish the natural dispositions and qualities of children rather than impose their tutors' designs and expectations upon them. Their common objections to Helvétius

nevertheless took different forms. While Rousseau decried materialism in general, Diderot took issue only with that crude variant which, on his understanding, reduced all thought to pure sensation. Whereas Rousseau mistrusted teachers who either believed or pretended that they spoke on God's behalf, Diderot was persuaded that God himself had been invented by man. He judged that Rousseau had fundamentally confused unsociability for selfreliance, and he showed no interest in promoting any scheme of negative education that might be fit for children freed from all dependence on others, like Robinson Crusoe learning to fend for himself.

Diderot's conception of human nature differs from Rousseau's in attributing more dynamic potentialities for change and self-improvement to each individual's seminal personality. If he had coined the term *perfectibilité*, which was in fact invented by Rousseau, it would have encapsulated his understanding of the spark of genius, the impulse of creativity and the moral formation of character. Yet both men agreed, in contrast with Helvétius, that education ought fundamentally to accord with human nature instead of recasting it. Each subscribed essentially to a belief in self-education, aiming to encourage children to follow their intuitions and thereby attain intellectual and moral maturity by being true to themseves. They also shared a profound mistrust of the superstitious idolatry that passed for a Christian education, proffered in priestly interpretations of the mysteries of Holy Writ. As opposed to the arcane dogmas of a revealed religion, they were drawn to the spectacle of creation and to the open book of nature. They both thought that education ought to be pursued endogenously, out of natural curiosity, accompanying the development of the human faculties, and never by indoctrination.

5 Vitalist materialism

It is hardly surprising that a philosopher who advocated that moral principles should be true to Nature, which he believed to be in a state of continual flux, should have found himself suspected of lack of consistency. Like his colleague and co-editor of the *Encyclopédie*, D'Alembert, he saw his own Age of Enlightenment as committed to a systematic spirit but not the spirit of system which had distinguished the principal contributions of seventeenth-century European philosophy. Although he was the author of a treatise on mathematics and geometry, he was more interested in matters of style, particularly with respect to painting, music and the theatre. His *Salons* (1759-81) comprise perhaps the principal contribution to art criticism in the eighteenth century, and his posthumously published *Essai sur la peinture (Essay on Painting)* (written in 1765) was to stir the imagination of Baudelaire and other admirers in the Age of Romanticism.

He is better described as an empiricist than as a rationalist, indebted more to the philosophical methods of Bacon and Locke than to those of Descartes and Leibniz. He was a materialist in denying the existence in man of an intangible spirit or soul, and over the course of his life he became a progressively more outspoken atheist, in rejecting all notions of either a transcendent or immanent God. As is most conspicuous from his so-called *Lettre à Landois* (1756) and his novella *Jacques le fataliste* (written in 1773) he was at once a philosophical determinist, convinced that Nature left no room for unpredictability or caprice, and at the same time a libertarian, who identified the fundamental dignity of human conduct in terms of autonomous agency and choice, in poignant recognition of the bittersweet paradox that to choose is to act from a motive beyond one's control.

Diderot's materialism drew more inspiration from the sciences of physiology and medicine of his day than from physics, since he perceived matter not as inert but as inherently active and self-animating, as a collecton of atoms in a seminal fluid in continual fermentation. He was struck by Haller's research on the sensitivity and irritability of organic matter and was most particularly impressed by Bordeu and the Montpellier School of physiological medicine, which excited his interest in the internal mechanisms that gave impetus to such matter and regulated its health. Like Montesquieu, he sought to investigate the dynamic forces and tensions which shape the conduct of both living bodies and social systems. To the extent that a number of human sciences would around the end of the eighteenth century come to address such issues as apparently more fundamental than the constitutional and legislative programmes of Enlightenment political theorists, Diderot may be regarded as a philosophical precursor of such change.

Michel Foucault's depiction in *Les mots et les choses: une archéologie des sciences humaines (The Order of Things)* (1966) of certain epistemic metamorphoses within the sciences of man that may be dated from around 1770 to 1800 could have embraced the materialist philosophy of Diderot in addition to the examples offered from economics, linguistics and biology (see Foucault, M.). Diderot's reflections on the organic forms and forces of social life and on the growth and decadence of civilizations might in the twentieth century have come to be termed

'structural-functionalism'. In his own day they illustrate an approach to the science of society which would progressively displace speculations about the moral dimensions of human conduct with investigations into its underlying, bodily or material, causes. They herald the advent of 'sociology' in the nineteenth century in so far as it was modelled upon eighteenth-century 'physiology'.

6 Central tenets in oblique articulations

Diderot's reflections on the arts, human nature and society were not only to strike his readers among romanticists and scientists alike as particularly modern. By virtue of his irregular and sometimes fitful literary style, his preference for the cut and thrust of the dialogue over the discursive finality of the treatise, and his pursuit of anonymity as the mysteriously unidentified author of his own texts, he anticipated some of the philosophical issues raised by postmodernist thinkers today, often in criticism of the so-called 'Enlightenment Project' as a whole. No major writer of the eighteenth century left so many of his principal works unpublished in his lifetime, even though several, including the best among them, had been drafted long before his death. No encyclopedist ever managed better to convey his own thoughts by way of plagiarism, insinuation, multiple cross-references and deliberately misleading notes and commentaries. In assuming the personae of historical figures whose ideas he transcribed in his own fashion, and of characters he invented in order to contradict himself, he succeeded more than any other eighteenth-century writer in bestowing independent life upon his work, in the act of creation releasing it from the pen of its author. Like Socrates in Plato's *Phaedrus* or Derrida in *De la grammatologie*, he sought to ensure that the dead hand of script would not count as his last word. Even through his writings Diderot's voice appears to speak aloud, weaving a conversation without end.

If coming to final conclusions was not his chief aim either as a philosopher or as an encyclopedist, a number of unsettled doctrines may nevertheless be ascribed to him as among his most significant contributions to eighteenth-century thought across several disciplines. First, he supposed that civilizations were like socially organic forms of life, marked by cyclical patterns of growth, maturity and decay, and by institutions which reflected the dynamic or repressive character of their moral or religious principles. In these beliefs, which above all inform his contributions, dealing with global history, to Abbé Raynal's *Histoire des Deux Indes (History of Two Indias)* (1772-80), he was guided both by Buffon's *Histoire naturelle (Natural History)* (1749-88) and by Montesquieu's *Esprit des lois (The Spirit of the Laws)* (1748).

Second, he held that biological attributes of human nature - including instincts for survival and companionship but also bodily weaknesses and mental stupidity endemic to solitary existence - made society both necessary and possible. His *Apologie de l'abbé de Prades*, together with several of his articles on political subjects for the *Encyclopédie*, make plain the influence upon him with respect to this subject of Pufendorf, as well as the double-edged nature of his rejection of Hobbes's and Rousseau's differing perspectives on mankind's isolated state of nature.

Third, he was convinced that moral rules which dictate human conduct could promote the general interest of a society only if they accorded with and gave free rein to the physical desires of its members. Both in *Le Rêve de d'Alembert* (1769) and the *Supplément au Voyage de Bougainville*, he put a case for the ultimate physicality of human nature, whose constituent matter he believed to be moved by vital forces which would ensure its natural development towards an appropriate morality unchecked by extraneous rules. Convinced that liberty and necessity went hand in hand, he saw certain features of Western civilization as injurious to freedom when they attempted to obstruct the determinate mechanisms of natural law, as was the case most particularly with religions whose codes of duty stifled the expression of usefully pleasurable passions, thereby harming both individual wellbeing and public peace. In the light of his philosophy, he would have emblazoned our churches and their attendant institutions with warnings of the hazards they pose to our health. He thought Christianity was not only the opiate of the people but a spiritually carcinogenic poison.

Fourth, he believed that political and social institutions needed to correspond as well to a population's national or regional temperament and to its level of development. Just as punishments would be tailored to crimes, so laws should fit the communities they serve and direct. In his *Observations sur le Nakaz* he claimed that the character of the Russian peasantry was ill-suited to the drastic reforms proposed by French physiocrats, while in the *Histoire des Deux Indes* he argued that the fresh freedoms won in America were unlikely to take root in the acidic old soil of Europe. If he would not categorically exclude a favourable meaning for the term 'enlightened despotism',

Diderot believed that good government was never harsh and that no people ought to be governed too much.

All of these principles of organic growth and adapatibility led Diderot to perceive human liberty in much the same way that Montesquieu described laws - that is, as a set of necessary relations deriving from the nature of things. The character of individuals must not be forced, he thought, but, in passing gradually and without impediment through the seasonal changes of their constitutions, whole populations naturally change themselves. As their nature changes, so too should their political systems. The metamorphoses of human development ought only to record the various stages of our species' spontaneous generation.

Dietrich of Freiberg (*c*.1250-after 1310)

In his work on the rainbow, De iride et radialibus impressionibus (On the Rainbow and Radial Impressions), Dietrich makes extensive use of experimental observation. He also wrote a number of other, more theoretical works including De esse et essentia (On Existence and Essence) and De intellectu et intelligibili (On Intellect and the Intelligible). In these works, Dietrich's emphasis varies; his theological works tend to be heavily Neoplatonic, while his more secular philosophical works are more Aristotelian. Dietrich disagreed with Aquinas on certain metaphysical issues, and seems to have written in opposition to particular works by Aquinas.

A Dominican from Germany, Dietrich studied at the University of Paris *c*.1275-7 and became master of theology at St Jacques in Paris before 1303. He was named provincial of Teutonia in 1293 and vicar provincial in 1310. He is best known for his investigations on the rainbow, put into writing by special request of the meeting of the general chapter of the Dominican order at Toulouse in 1304. The resulting work, *De iride et radialibus impressionibus (On the Rainbow and Radial Impressions)* draws on the optical theories of Alhazen, but in addition takes a new approach to researching the causes of the rainbow. Dietrich's innovation, as Boyer (1959) explains, was to see the value of investigating the reflective and refractive properties of individual raindrops rather than of the rain cloud taken as a whole. Extensive experimental observations of the paths of light rays through glass spheres and beakers filled with water enabled him to deduce how light passes through raindrops to produce both the lower and upper bows of rainbows. This part of his theory would not be further refined until the time of Descartes. His explanation of how colours are produced in the rainbow was less enduring, but is well thought out and closely argued (see Natural philosophy, medieval).

Dietrich also wrote on a wide range of other topics in natural philosophy, logic, psychology, metaphysics and theology. Other works in natural philosophy are less oriented toward experimental evidence: they include short works on the four elements and their compounds, on light and colour, on time and on astronomy. In his less experimental works, and particularly in his theological works, Dietrich displays extensive knowledge of and interest in Neoplatonic as well as Aristotelian theories. In the theological work *De intellectu et intelligibili (On Intellect and the Intelligible)*, for example, Dietrich describes creation as intellectual emanation through a hierarchy of Intelligences beginning with the primary intelligence - the soul of the first firmament - and progressing down to the world of man. Gilson (1955) has characterized the cosmology Dietrich sets forth here as a restatement of Proclus using Aristotelian terminology. This aspect of Dietrich's thught was to influence German Dominican mystics such as Meister Eckhart.

In his psychology, Dietrich rejects the Averroistic notion of a separate, shared agent intellect (see Averroism). Instead, Dietrich argues that there is an individual agent intellect always in action within each person. Thus far most thinkers of his time would have agreed, but Dietrich's account of the role of the agent intellect in human knowledge is once more strongly Neoplatonic. In his view, intellectual knowledge cannot be explained by the process of abstraction alone; an act of the agent intellect is required to make the object of cognition intelligible. The agent intellect is able to carry out this operation of intuitive cognition because it is made in the image of the divine intellect, proceeding from the divine ideas as an image and likeness of total being. Since, as an image of the divine, the human agent intellect comprehends all being, it is capable of knowing all other things by virtue of its knowledge of itself and as a feature of its orientation toward God (see Platonism, medieval).

Dietrich disagrees with Aquinas on certain important metaphysical issues. Maurer (1956), in his edition of Dietrich's *De quidditatibus entium (On The Essential Natures of Things)*, has argued that both this work and *De esse et essentia (On Existence and Essence)* were written in opposition to Aquinas' *De esse et essentia*. Dietrich denies Aquinas' argument that there is a distinction between essence (*essentia*) and existence (*esse*) in reality. The fact that we can understand a rose without knowing if one exists does not force us to acknowledge a real distinction between the rose's existence and its essence, by Dietrich's account, but merely shows that there are two ways of knowing about the rose. The only difference between essence and existence that Dietrich allows is in their manner of signifying being: *esse* signifies being as actuality, while *essentia* signifies it as disposition to actuality. Several other differences with Aquinas follow from this important fundamental disparity. To give one important example, Dietrich denies that it is in any way possible for accidents to exist without a subject, an argument that

puts in question Aquinas' explanation of transubstantiation.

Digby, Kenelm (1603-65)

Seventeenth-century English Catholic, original member of the Royal Society, and one of the first philosophers to produce a fully developed system of mechanical philosophy, Sir Kenelm Digby cut a dashing figure as a poet, privateer and philosopher. As a Catholic and royalist, he spent much of his life in semi-exile on the continent where he conversed with many of the political and intellectual leaders of his time; as a philosopher, he was favourably compared to René Descartes and John Locke. He attempted to wed the philosophy of Aristotle to the new mechanical physics, which maintained that every event in the material world is reducible to matter in motion. His interests and writings cover a wide range, from religion and magic to vegetative growth and literary commentary. The explicit goal of his most significant book, Two Treatises (1644), was to prove the immortality of the human soul. To this end, the first treatise constitutes an exhaustive study of bodies and their features. By showing that all corporeal qualities are to be explained in strictly material terms, he prepares the way for a thorough discussion of the soul. Digby argues that the soul must be immaterial (and hence immortal) because otherwise its features cannot be explained. He went on to apply the mechanical principles which he developed in this work to a variety of topics, including some traditionally associated with the occult. His works on alchemical, medical and religious topics were also widely read.

1 Life

Sir Kenelm Digby was one of the most colourful and impressive figures of his generation. He was not yet three when his father, Sir Everard Digby, was tortured and executed for his role in the Gunpowder Plot. As a Catholic at Oxford (1618-20), the young man was forced to remain on the periphery of the university. He studied there with the mathematician and astronomer, Thomas Allen, who probably introduced him to alchemical experiments. He travelled to France, Spain and Italy (1620-3) where a prince considered him ‘the just measure of perfection’ and Marie de Medici made immodest advances. A friend to such writers and artists of his era as Ben Jonson and Anthony van Dyck, and to members of the English royal family, Digby was knighted by James I, was a successful privateer for Charles I, and chancellor to Queen Henrietta Maria. In 1625 he married Venetia Stanley, famous for her beauty and intellectual achievements, with whom he had five children, and whose sudden death in 1633 turned his attention from public concerns to philosophical contemplation. The first two years of a lengthy period of mourning were spent in secluded study at Gresham College, London, in whose laboratories he conducted experiments. Digby converted to Anglicanism in 1630 (possibly for political reasons), but reconverted before he moved to France in 1635, where he felt more comfortable as a Catholic.

Although under suspicion in England as a Catholic and ardent royalist, and briefly imprisoned there (1642-3), he often travelled from France and even negotiated with Cromwell in 1648 and 1654-5 for toleration of Catholicism in England. After his reconversion, he turned his attention to religious and ecumenical issues and published *A Conference with a Lady about Choyce of Religion* (1638) and a response to Thomas Browne’s popular *Religio Medici* entitled *Observations upon Religio Medici*, the latter written in 1643 while he was in prison. During his many years in Paris, he was part of the Mersenne circle, studied anatomy and chemistry, published his *Two Treatises* (1644), and was one of the early admirers of Descartes’ *Discourse on Method*. He conversed and corresponded with Hobbes and Descartes, both of whom seem to have thought well of him. Along with his mentor and fellow English Catholic, Thomas White, Digby was one of the first Englishmen to produce a fully developed system of mechanical philosophy. He applied the mechanical principles which he developed in his *Two Treatises* to a variety of topics. He collected medical, chemical, and household remedies as well as books and manuscripts. Many of his recipes and remedies, which he exchanged with other natural philosophers including Robert Boyle, were published after his death. Digby went to Montpellier in 1657 to take the waters and there gave his famous account of the powder of sympathy. This led to his most popular book, *A late Discourse Made in a Solemne Assembly… touching the Cure of Wounds by the Powder of Sympathy* (1658 - originally in French), which was reprinted often and translated into a number of languages. Digby travelled to Germany, the Low Countries and Scandinavia; in 1660, after the Restoration, he returned to England, where he was one of the original members of the Royal Society. He presented his *A Discourse Concerning the Vegetation of Plants* to the Society in 1661. Although Digby’s works were soon superseded, he was highly regarded in his day. As a contemporary wrote, he was: ‘This Ages Wonder for his Noble Parts, Skilled in six Tongues, and learned in all the Arts’.

2 The *Two Treatises*

Digby published his *Two Treatises* in Paris in 1644 with the professed goal of proving the immortality of the soul. In the dedicatory epistle he makes plain that he desires to analyse bodies because ‘the knowledge of them serveth to the knowledge of the soul’, that is, through an exhaustive account of the nature of bodies and their qualities, he hopes to show that features of the human soul are not ‘effected by corporeall agents’, and hence must have something immaterial as their source. In his preface, Digby is particularly clear about his method. Against the scholastics who achieve neither science nor certitude, but attribute to bodies ‘hidden qualities that mans witt cannot reach unto’, Digby intends to begin with ‘the commonest thinges’ in nature so as ‘to shew from what principles, all kindes of corporeall operations do proceed; and what kind of operations all these must be, which issue out of these principles’. By arguing in his first treatise that corporeal qualities can be explained wholly in terms of the material constituents of bodies and without any reference to occult powers, Digby prepares the way in his second treatise for his argument for the immortality of the soul. As he puts it in his preface, he intends to ‘raise’ his discussion in the second treatise ‘to the contemplation of the soule; and shew, that her operations are such, as cannot proceed from those [mechanical] principles; which being adequate and common to all bodies, we may rest assured, that what cannot issue from them, cannot have a body for its source’.

In the *Two Treatises* Digby interweaves ancient and modern principles into an Aristotelian fabric. He has unmitigated scorn for the scholastics and high esteem for contemporaries like Descartes and Galileo. But whereas the latter mechanists explicitly reject the Aristotelian philosophy, Digby embraces it (see Aristotle). He asserts in the conclusion to the first treatise that his proposals ‘are built upon the same foundations’ as Aristotle whom he describes as: ‘the greatest Logician, Metaphysitian and Universall scholler… that ever lived’. Aristotle’s ‘name must never be mentioned among schollers, but with reverence, for his unparalleled worth; and with gratitude for the large stocke of knowledge he hath enriched us with’. But Digby is equally explicit about the fact that for the true science, we must inform Aristotelian principles with the new discoveries: ‘Let us then admire him for what he has deliver’d us: and where he falls short or is weary in his search… let us seek to supply and relieve him’ (1644: ch. XX).

Defining body in terms of quantity, and quantity in terms of divisibility, Digby offers an account of bodies and their qualities in mechanical terms. He uses rarity and density, which he describes as the different ways in which something is divisible, to explain the four elements of Aristotle. He maintains that his analyses of Aristotle’s four elements are ‘the proper notions of the four elements… which are, the notions of Quantity’ (1644: ch. IV). He applies the principles of force and velocity to these elements and then ‘deduces’ the principles ‘which govern Mechanics’ (1644: ch. IX). From the features of these ‘most simple bodies’ or elements, Digby intends to explain the qualities and operations of all the ‘compounded’ bodies of nature, both animate and inanimate. He acknowledges in his conclusion that he departs from Aristotle on a ‘few points’, but insists that his fundamental principles are Aristotle’s: ‘all the difference between us is, that we enlarge ourselves to more particulars then he hath done’.

In his criticism of the scholastic philosophy, Digby nicely exemplifies the transformation under way in seventeenth-century thought. The mechanical physics had brought about a radical re-evaluation of a number of doctrines which the scholastics had promulgated for centuries. Digby was particularly articulate concerning the ontology of the objects of perception. On this topic, he shares many of the same doctrines, if not the same depth of thought, of John Locke (see Locke, J. §§4-5). According to the scholastic tradition, sensible qualities were treated as irreducibly distinct attributes of the object of perception. The sensible quality of colour, for instance, was believed to exist in essential relation to sight and was not considered reducible to any other attribute in the object. Digby rejected as unintelligible this tendency ‘to give actual Beings to the quantity, figure, colour, smell, taste and other accidents’ of the object, ‘each of them distinct one from another, as also from the substance which they clothe’. His point was that just ‘because I find the notions of them really distinguished… in my mind’ I should not act ‘as if there were different Entities’ (1644: ch. I). According to Digby (and Locke), the sensible accidents of the scholastics in fact have no separate or distinct existence in reality. Rather, ‘what is but one entire thing in it self, seemeth to be many things in my understanding’. However separate these qualities may be in the mind, they are but aspects of a single, unitary thing in reality. According to Digby, this unitary thing consists of corpuscles of matter in motion which in turn cause motions in the surrounding matter. Some of these motions pass through both the medium and the sense organs until they reach the brain of the perceiver and there cause an appropriate idea in

the mind. The multiplicity of the qualities which we perceive are therefore due not to a multiplicity in the object but rather to one in the sense organs. According to Digby, the senses ‘make severall and distinct pictures of what entereth by their doors’ and thereby constitute a different way in which the object can cause motions and hence ideas in us (1644: ch. I).

Having made an exhaustive study of bodies and their features in his first treatise, Digby turns his attention to matters immaterial in his second. By showing that all corporeal qualities are to be explained in strictly material terms, he has prepared the way for his discussion of the rational soul and its qualities. At this point he acknowledges that we ‘have passed the Rubicon of experimental knowledge’ so that ‘henceforth, we must in all our searches and conclusions rely upon the single evidence of Reason’. Digby claims that when we are stripped of everything material ‘there still remaineth a *substance*, a *thinker*, an *Ego* or *I*’ (1644: ch. IX). His argument for immortality is fairly standard. He defines the soul as that which is immaterial and indivisible and notes that only something material can undergo the decay and dissolution which mortality requires. That is, since ‘no change at all can happen to an abstracted soul’, it is incapable of mortality (1644: ch. XII).

Digby’s *Two Treatises* was widely read and generally well received by his contemporaries. His physical proposals, however, did not make a lasting contribution. Digby himself offers the most likely explanation for their failure in his dedicatory epistle: ‘a gallant man, whose thoughts flye att the highest game… deemeth it farre too meane for him, to dwell upon the subtilest of their mysteries for science sake’. In the end, Digby’s mechanical physics was too imprecise and incomplete; the treatises could not compete with the more fully articulated physical systems of Galileo, Descartes and Gassendi.

3 Other works

Digby applied himself to topics ranging from alchemy and plant growth to religion and literature. Of special interest to philosophers is the fact that he was prepared to extend the mechanical principles developed in the *Two Treatises* to all of his scientific and philosophical studies, even to topics traditionally associated with the occult. He practised alchemy, but agreed with many of his contemporaries that its language and method should be made more precise. He studied and conversed with Nicolas le Fèvre and other chemists-alchemists on the continent and, like them, was inclined to turn alchemical experiments into precise chemical events. Some of the results of his studies appear in his *A Choice Collection of Rare Chymical Secrets and Experiments in Philosophy*, published posthumously in 1682.

Digby also studied medicine: he both collected and experimented with medicinal recipes and, like many of his contemporaries, he was interested in the Paracelsian tradition of sympathetic medicine (see Paracelsus). Digby agreed with his Paracelsian predecessors that a wound could be healed by treating an object that contained blood from it (say, the sword that had caused the wound or bandage that had bound it). He was convinced that the Paracelsians were correct, since he had successfully cured a serious wound by such means. He diverged significantly from the tradition, however, in his explanation of the effectiveness of the treatment: whereas the Paracelsian explanation was based on occult virtues and hidden sympathies, Digby’s explanation relies on mechanical principles. In his book on the powder of sympathy, Digby presents the seven physical principles from which his explanation is supposed to follow and then proposes that because the medicine ‘being incorporated with the blood cannot choose but make the same voyage together with the atoms of blood’, and because ‘there will be a kind of current of air drawn round about the wound’, it follows that the blood on the object treated with the medicine will find ‘the proper source and original root whence they [the atoms of blood] issue’ and ‘will joyntly be imbibed together [with the medicine] within all the corners, fibres, and orifices of the Veins which lye open about the wound; when it must of necessity be refresht, and in fine imperceptibly cured’. Thus Digby explains the traditional medical ‘fact’ by modern means.

While some of his alchemical and medical opinions placed him in a tradition that was soon supplanted, Digby was at the forefront of the science of biology. In his *A Discourse Concerning the Vegetation of Plants*, which he presented to the nascent Royal Society in 1661, he attempts to explain plant growth by chemical and mechanical means. In his analysis of the growth and decay of plants, he relies on his notions of the four elements and their characteristic ‘actions’. He gives a very clear description of the germination, development, and reproduction of plants and uses an observational technique very accurate for the time. While neither so colourful nor so popular as his book on the powder of sympathy, this work was probably his most significant scientific offering.

Dignāga (*c*.480-*c*.540)

A logician and epistemologist, Dignāga is traditionally regarded as the founder of a Buddhist school that sought to avoid divisive controversies over which Buddhist writings were authentic by emphasizing logic and epistemology rather than the study of scriptures and their commentaries. His principal contributions consisted of refining the theory of inference and tightening the forms of argument commonly used in debate and polemics. His theories became the basis on which the influential philosopher Dharmakīrti built his system, which became the standard Buddhist scholastic system in India and later in Tibet.

1 Epistemology

According to traditional hagiographies, Dignāga was born around 480 into a Brahman family near Kāñcīin south India, where he was ordained a Buddhist monk as a young man. Dissatisfied with his teachers in the south, he is supposed to have travelled north and become a disciple of Vasubandhu. Celebrated for his debating skills, he was nicknamed the 'Bull in debate'.

At the beginning of his principal work, *Pramāṇasamuccaya*, Dignāga stated that his purpose was to resolve several controversies that other philosophers had generated about the means of acquiring knowledge. Whereas his predecessors had enumerated several methods by which knowledge may be acquired, Dignāga took the position that there are in fact only two methods. These two methods are distinguished from one another in virtue of the kinds of object that can be their subject matters. The first method of securing new knowledge is described as pure sensation (*pratyakṣa*), a form of cognition that is free of all judgment (*kalpanā*). The subject matter of this type of cognition is particular instances (*svalakṣana*) of colour, sound and other sensible properties. The second method is described as inferential reasoning. The subject matter of this type of cognition is universals (*sāmānyalakṣaṇa*). In contrast to most Brahmanical philosophers WHO had preceded him, Dignāga held that only the senses can be aware of particular sensations, and only the intellect can be aware of universals. The view that there are exactly two types of knowledge, and that there is no subject matter common to both of them, came to be a hallmark of Buddhist doctrine, since it was accepted by most Buddhist philosophers writing in Sanskrit and rejected by the majority of Brahmanical and Jaina philosophers (see Epistemology, Indian schools of §1).

Before Dignāga, most Indian treatises dealing with reasoning were primarily devoted to outlining the rules of debate between opposing parties. Consequently, discussions of the formal properties of correct lines of argument were mingled with discussions of which errors on a discussant's part would result in defeat. Dignāga is usually given credit for being the first Indian philosopher to make a clear distinction between the formal properties of correct reasoning and the rules of debate. Debate, he said, is merely the articulation for the benefit of another person of a conclusion that one has arrived at by oneself through correct reasoning.

A correct inference, said Dignāga, is one that makes use of an observable property that serves as a sign (*liōga*) of an unobserved property. The object to which the signifiable property can be inferred to belong is called the subject (*pakṣa*) of the inference. One property can serve as the sign of a second property only if three conditions are met. First, the sign must be observed to be a property of the subject of the inference. Second, the sign must be known to occur together with the signified property in objects other than the subject of the inference. And third, the sign must not be known to occur in objects in which the signified property is absent (see Inference, Indian theories of).

2 Theory of language

In contrast to the Brahmanical philosophical traditions, Buddhist and Jaina philosophers denied the authority of the Veda, the sacred texts on which the Brahmanical religion was based. According to Brahmanical philosophers, these sacred texts came from a nonhuman source and were infallible. Brahmanical philosophers tended to argue that human perception and reasoning are always liable to error, and human beings must therefore appeal to superhuman sources of knowledge if they are ever to have certainty. Moreover, human knowledge is ultimately limited to what can be known through the senses, and it requires a special source of knowledge such as the Veda to make people aware of duty, the merit that attends doing one's duties, and the rewards of earning that merit. The language of the Veda was regarded as different from all ordinary human languages in that it is eternal (see MīmāṃsāČsect;3). All of these Brahmanical doctrines were repudiated by Dignāga, who held that all sentences,

including those of the Veda, are merely a special kind of sign that function in essentially the same ways as any other kind of inferential sign. Since language is merely a species of inference, information communicated through language is no more reliable than information gained through reasoning. And like all other inferential knowledge, the knowledge communicated through language does not convey positive information about things but merely eliminates certain states of affairs from consideration. Dignāga argued that language cannot express the particulars that are known through the senses; rather, verbal symbols express only concepts generated by the mind. These concepts are formed not by observing universals or similarities that are sensed in particulars, but by ignoring the differences in what is observed.

3 Influence

Although Dignāga was honoured for centuries in India and Tibet as the founder of the Buddhist epistemological movement, his works were eventually superseded by his followers, the most notable of whom were Dharmakīrti, Dharmottara, Śāntarakṣita and Kamalaśīla in India, and Tsong kha pa Blo bzang grags pa and mKhas grub dge legs dpal bzang po in Tibet. Although a few of Dignāga's minor works were translated from Sanskrit into Chinese, none of his most important writings, and virtually none of the writings of his followers, were studied in China. Consequently, the epistemological school of Buddhism never developed in China and other parts of East Asia. After the demise of Buddhism in Northern India, the Sanskrit originals of most of Dignāga's works were gradually lost and nearly forgotten. In the early twentieth century, historians of Indian philosophy began to take a renewed interest in studying his works (mostly in Tibetan translations) and assessing his place in the evolution of Indian theories of inference.

RICHARD P. HAYES

List of works

Over twenty philosophical writings have been attributed to Dignāga. Of these, seven are no longer extant. The remaining works are extant only in Tibetan or Chinese translation. The following list includes only those for which studies or translations in European languages are available.

Dignāga (*c.*520) *Ālambanaparīkṣa (Examination of the Object of Awareness)*, trans. S. Yamaguchi, 'Examen de l'objet de la connaissance (*Ālambana-parīkṣa*): textes tibétains et chinois et traduction des stances et du commentaire éclaircissements et notes d'après le commentaire tibétain de Vinītadeva' (Examination of the Object of Awareness: Tibetan and Chinese texts, with translation of illuminating stanzas and commentary, and notes after Vinītadeva, *Journal Asiatique* (January-March): 1-59, Paris: Imprimerie Nationale, 1929; also trans. F. Tola and C. Dragonetti, 'Dignāga's *Ālambanaparīkṣavṛtti*', *Journal of Indian Philosophy* 10: 105-34, 1982.(A brief work in eight verses that investigates various possibilities for what the exact nature of the content of a sensory cognition is.)

Dignāga (*c.*525) *Nyāyamukha (Introduction to Systematic Reasoning)*, trans. G. Tucci, *The Nyāyamukha of Dignāga*, Heidelberg: Materialien zur Kunde des Buddhismus, 1930.(An introductory work on the methods of correct reasoning.)

Dignāga (*c.*530) *Pramāṇasamuccaya (Collected Writings on the Acquisition of Knowledge)*, first chapter translated in Hattori, M., *Dignāga, On Perception*, Cambridge, MA: Harvard University Press, 1968; excerpts of chapters two and five translated in Hayes, R.P., *Dignāga on the Interpretation of Signs*, Dordrecht: Kluwer Academic Publishers, 1988.(A collection of writings on epistemology, with sections on sense perception, inference, debate and theory of language.)

Dilthey, Wilhelm (1833-1911)

Wilhelm Dilthey saw his work as contributing to a 'Critique of Historical Reason' which would expand the scope of Kant's Critique of Pure Reason by examining the epistemological conditions of the human sciences as well as of the natural sciences. Both kinds of science take their departure from ordinary life and experience, but whereas the natural sciences seek to focus on the way things behave independently of human involvement, the human sciences take account of this very involvement. The natural sciences use external observation and measurement to construct an objective domain of nature that is abstracted from the fullness of lived experience. The human sciences (humanities and social sciences), by contrast, help to define what Dilthey calls the historical world. By making use of inner as well as outer experience, the human sciences preserve a more direct link with our original sense of life than do the natural sciences. Whereas the natural sciences seek explanations of nature, connecting the discrete representations of outer experience through hypothetical generalizations and causal laws, the human sciences aim at an understanding that articulates the fundamental structures of historical life given in lived experience. Finding lived experience to be inherently connected and meaningful, Dilthey opposed traditional atomistic and associationist psychologies and developed a descriptive psychology that has been recognized as anticipating phenomenology.

Dilthey first thought that this descriptive psychology could provide a neutral foundation for the other human sciences, but in his later hermeneutical writings he rejected the idea of a foundational discipline or method. Thus he ends by claiming that all the human sciences are interpretive and mutually dependent. Hermeneutically conceived, understanding is a process of interpreting the 'objectifications of life', the external expressions or manifestations of human thought and action. Interpersonal understanding is attained through these common objectifications and not, as is widely believed, through empathy. Moreover, to fully understand myself I must analyse the expressions of my life in the same way that I analyse the expressions of others.

Not every aspect of life can be captured within the respective limits of the natural and the human sciences. Dilthey's philosophy of life also leaves room for a kind of anthropological reflection whereby we attempt to do justice to the ultimate riddles of life and death. Such reflection receives its fullest expression in worldviews, which are overall perspectives on life encompassing the way we perceive and conceive the world, evaluate it aesthetically and respond to it in action. Dilthey discerned many typical worldviews in art and religion, but in Western philosophy he distinguished three recurrent types: the worldviews of naturalism, the idealism of freedom and objective idealism.

1 Foundation of the human sciences

Dilthey initially studied theology at Heidelberg and Berlin, but increasingly devoted his attention to history and philosophy. Before completing his dissertation on Schleiermacher's ethics in 1864, he had already written a long prize-essay, 'Das hermeneutische System Schleiermachers in der Auseinandersetzung mit der älteren protestantischen Hermeneutik' (Schleiermacher's Hermeneutic, A System in Relation to Earlier Protestant Hermeneutics) (see Schleiermacher, F.D.E.). After teaching at Basel, Kiel and Breslau, Dilthey was appointed in 1882 to the chair in philosophy in Berlin that Hegel had once occupied. His more empirical approach to the understanding of history departs from Hegel in being radically multidisciplinary. Dilthey's contributions to cultural and social history, to literary criticism and to the history of the human sciences in general found their philosophical grounding in a major, although unfinished, theoretical work, *Einleitung in die Geisteswissenschaften* (*Introduction to the Human Sciences*) (1883, 1982).

In 1883, Dilthey published the first of two projected volumes of this work. Book One of the *Einleitung* was devoted to an overview of the human sciences; Book Two to a history of the rise and fall of metaphysics in relation to the project of grounding the natural and human sciences. At the end of this history he maintains that both metaphysics and the modern natural sciences have established false models for the human sciences by constructing abstract intelligible worlds independent of lived experience. A new epistemology is needed which will show that the modern scientific conception of nature is a mere phenomenal abstraction from the more inclusive reality of life. Dilthey introduces the idea of a life-nexus (*Zusammenhang des Lebens*) as the original matrix of reality, not only for the human sciences, but also for the natural sciences. If the natural sciences find it useful to explain phenomena

by means of elemental entities and universal mechanistic laws, this does not entail that they possess a more ultimate reality than the human sciences or that the latter should be constrained to drop the idea of purposiveness from their understanding of history and society.

Dilthey shows that in the past the human sciences were blinded by the success of natural science to adopt its mechanistic approach. Inspired by the ideas of Hobbes, Spinoza and Hume, a natural system of the human sciences was formed (see Hobbes, T. §2; Hume, D. §1; Spinoza, B.). A theoretical analysis of human nature was to establish ‘a few general psychic elements to explain the facts of human historical life’. These psychological elements and a finite number of non-teleological laws, like that of self-preservation, were supposed to explain the mysteries of life, the intricacies of human action, and the complexities of social interaction.

Even more problematic than the reductive character of this natural system of the human sciences is the fact that from the traditional epistemological perspective the separate foundations of the natural and the human sciences mark a division within theory alone. This has the unfortunate effect of relegating practical philosophy to a secondary concern. Dilthey disapproves of the abstract way in which a purely theoretical approach to the human sciences seeks the explanative basis for the value judgments and the imperatives that regulate the life of the individual and society. The proper foundation of the system of the sciences must be located in ‘self-reflection’ in contrast to ‘theory of knowledge’. Self-reflection based on our experience of life provides the foundation for action as well as for thought. This philosophical self-reflection renders theory and practice equiprimordial.

The real task of founding both the natural and the human sciences was left for the second volume of the *Einleitung*, but Dilthey did not publish it during his lifetime. He did, however, work out a large part of it, which first appeared in 1982 in Volume 19 of the *Gesammelte Schriften (Collected Works)*. Dilthey examines the conditions of consciousness involved in our prescientific awareness of reality. He begins Book Four with a first principle, that of phenomenality, according to which everything real is accessible as a fact of consciousness without being reduced to a mere representation of consciousness. It is important to point out that Dilthey’s conception of phenomenality should be contrasted to phenomenalism, which reduces all reality to facts of consciousness (see Phenomenalism). Nor is it to be confused with the view that facts of consciousness are mere phenomena as distinct from external reality. Dilthey shows how the facts of our consciousness possess a primordial reality that already contains a reference to things beyond consciousness. When we become aware of something *as* a fact of consciousness we possess what Dilthey calls *Innewerden* or ‘reflexive awareness’. This reflexive awareness is pre-reflective and involves a felt self-givenness but no explicit sense of self. *Innewerden* is thus not to be equated with an objectifying self-consciousness, for it precedes any subject-object, act-content distinction. Reflexive awareness is proto-intentional in that it is oriented towards the world even if the world is not yet thematized as an external objective domain. It is this sense of being already a part of the world that is lost in the natural sciences, but must be preserved in the human sciences. Dilthey’s initial descriptions of the facts of consciousness constitute an empirical phenomenology and are at the level of prescientific *Wissen* or immediate knowledge.

Dilthey’s second principle, that of self-reflection, allows him to move to the level of scientific *Erkenntnis* or conceptual knowledge. In reflexive awareness we possess the felt reality of the facts of consciousness, but this does not entitle us to posit their reality conceptually. The move from the first level of prescientific reflexive awareness to conceptualization is one of explication, where the reflexive becomes reflective. The principle of self-reflection explicates the facts of consciousness into an overall nexus that encompasses all aspects of psychic life.

Within this framework of total consciousness, self-reflection then begins to differentiate between facts of self-consciousness and facts of the world. Facts that are perceived as existing in my consciousness are grasped as part of inner perception. Those facts that are independent of my self are considered facts of outer perception. But the distinction between self and world is not one that can be derived from the intellect alone. The reality of the external world is not an inference based on causal hypotheses, but is felt primarily through resistance to the practical impulses of the will.

Dilthey proceeds to show that a reflexive or felt awareness accompanying acts of will provides a crucial step in the process of differentiating self and world. Through the felt tension between efficacy of the will and resistance to it we learn to distinguish the reality of inner perception from outer perception. This dynamic relation to the external world is more fundamental than the static epistemological relation of a representation to an object. Whereas

representational consciousness projects the world as a theoretical horizon for objects of natural science, reflexive awareness possesses the world as a temporal nexus in which I participate, but which is also full of things and persons actively resisting my will. A new, reflective epistemology of the human sciences must reclaim our original access to life and thus cannot be merely an extension of the epistemology of the natural sciences.

Book Five again does not restrict itself to the human sciences, but considers the logical conditions that determine all acts of representing reality. It provides Dilthey's logic, not as a formal logic that abstracts from reality, but as an intermediary between the epistemological and methodological approaches to all the sciences that represent reality. Being representational, thought leaves behind the immediate certainty of reflexive awareness, but gains the capacity to apprehend truth. Thought is the attentive 'positing of reality' (*das Wirkliche*) not simply as that which momentarily resists, but as that which 'realizes a constant effect' (*das Wirkende*). Whereas perception posits as the real the shifting contents of what happens to be present, thought creates a nexus of representations that is in agreement with a system of reality that remains more or less constant.

The sixth and last book of the *Einleitung* begins with a general discussion of method and how it makes explicit the procedures for grasping reality inherent in the logical operations of thought. Dilthey distinguishes methods recurring in every domain of human knowledge from those peculiar to particular problems. The latter kind of method constitutes what Dilthey calls a higher logic which establishes 'rules of procedure that arise when a particular set of real conditions is introduced'. Dilthey is still speaking of both natural and human sciences, for he claims that 'aspects of mathematics, higher criticism, hermeneutics, jurisprudence [and] statistics belong to this higher logic'. It is only at the level of higher logic that we can begin to differentiate methodologically between the natural and the human sciences in specific ways.

The task of analysis and synthesis in the sciences is to simplify reality conceptually and to reorganize it in more systematic terms. Related to the process of analysis is the process of abstraction. The difference is that abstraction starts with a complex whole, 'singles out one fact and disregards the others, whereas [analysis] seeks to apprehend the majority of the facts that make up the factors of a complex whole'. Abstraction can occur in both the natural and the human sciences, but applies especially to the former. To the extent that analysis moves from a whole to its parts without isolating them from this whole, it can be said to engender understanding in the human sciences.

2 Descriptive psychology

Dilthey's 'Ideen über eine beschreibende und zergliedernde Psychologie' ('Ideas Concerning a Descriptive and Analytic Psychology') (1894) aims to wean psychology away from naturalistic models and redefine it as a human science. This new psychology would be 'first' within the system of the human sciences in the sense that it provides neutral descriptions of experience. It must suspend the general hypotheses of traditional psychology as much as possible, whether they be psychophysical or associationist. Such hypotheses strive to explain all psychic processes as different constructions from certain basic mental elements, such as representations. However, these elements cannot be well-determined or measured, with the result that hypotheses relating them have remained largely untestable.

Most psychological hypotheses about the association of representations are dispensable because inner experience is already interconnected. Whereas outer experience presents us with many unconnected phenomena which can only be related through the hypotheses of the natural sciences, psychology must consult the data of inner experience which are given as parts of a real continuum. This means that connectedness in psychic life does not need to be explained hypothetically, but can be experienced directly.

However, Dilthey does not altogether rule out hypotheses from his descriptive psychology. They are merely prevented from assuming the fundamental role they play in the natural sciences. It is clearly necessary to construct particular hypotheses when the continuity that normally exists among psychic processes is broken or interrupted. Also in cases where we were not fully attentive, questions of detail may remain problematic and thus require hypotheses to clarify what might have happened. Whereas explanative psychology *qua* natural science begins with general hypotheses, descriptive psychology may end with particular explanative hypotheses.

So far psychology has been considered mainly in relation to the description of inner experience. It should be pointed out that for Dilthey inner experience is not purely inwardly directed or introspective. Inner experience is often about external objects, but focuses on our attitude towards them. It is therefore in some way more

encompassing than outer experience, which excludes subjective attitudes. To move beyond this paradox Dilthey developed a new conception of experience that replaces the Kantian term *Erfahrung* with *Erlebnis* (lived experience). Lived experience is experience in its most inclusive sense and ‘contains a relation of inner and outer’.

Because lived experience discloses the original continuum of psychic life, it becomes necessary to reformulate the traditional conception of understanding which had been oriented primarily to our discrete outer experiences of natural phenomena. According to Kant, our experience of nature involves a discursive faculty of understanding (*Verstand*) that proceeds synthetically from partial representations to construct objective wholes (see Kant, I. §§6-7). Dilthey’s attack on faculty psychology undermines Kant’s pure intellectual conception of *Verstand*, which constructs the world in terms of fixed, abstract categories. When Dilthey speaks of understanding he means a very different process of *Verstehen*, which is concrete and develops historically. In so far as the *Verstehen* (understanding) of psychic life is based on lived experience it can be intuitive and proceed from the whole to the parts.

Kant’s *Verstand* as intellectual faculty was really geared to the scientific explanation of natural events. It allows us to relate the phenomena of nature, but provides no insight into their underlying reality. Dilthey accepts this limit for our knowledge of nature, but not for the understanding of ourselves and others. We cannot really understand nature, because it is not of our own making. Dilthey aligns himself with Vico by claiming that we can only truly know what we have ourselves made or contributed to (see Vico, G. §6). We thus have an access to psychological, social and historical reality - a recognition of ourselves in others, so to speak - which is impossible in relation to nature. Understanding constitutes the main goal of the human sciences in the way that explanation defines the natural sciences.

The fact that Dilthey points to the limits of scientific explanation has given some the mistaken impression that understanding is irrational. While explanation may be conceived as a purely intellectual process, understanding should not be characterized antithetically as a product of mere feeling or empathy. Lived experience does provide an immediate sense of the whole, but understanding, in appealing to all the powers of the psyche, does not overlook the intellectual processes. Sometimes understanding and explanation converge. Since understanding is contextual, it may need to bring external factors to bear which will then play a subordinate explanative role. Similarly, the description of lived experience must go over into analysis to bring out implicit structural relations more clearly.

There is an interdependence between the cognitive, emotive and volitional aspects of our consciousness which is at once structural and dynamic. While Dilthey begins with a discussion of representations, they are not considered as the underlying elements, with feelings and acts of will reduced to mere functions of representations. In some cases, representations may produce certain feelings which lead to a disposition to act. But in turn, representations themselves receive retroactive influences from our feelings and volitions. Clearly no aspect of psychic life can be understood in isolation or as most basic.

Dilthey regards development as a process of articulation whereby an indeterminate psychic continuum is differentiated into more distinctly related parts of a structural whole. The psychological concept especially formulated to define this formation of the self is that of the ‘acquired nexus of psychic life’ (*erworbener Zusammenhang des Seelenlebens*). This acquired psychic nexus embodies the history of the development of an individual and reveals the structural ordering of past experience. Encompassing knowledge of the world, evaluations and dispositions to act, it orients all present and future experience.

The individuality of the self is defined in terms of the structural articulation of the acquired psychic nexus. No qualitative uniqueness need be posited to explain individuality. What serves to distinguish individuals from one another is that the commonly held traits are manifested with differing forcefulness. In a given person, some qualities may be so faintly exhibited as to be, in effect, unobservable, others with such strength that we tend to notice them alone.

Dilthey’s discussion of individuality reflects one of the most pervasive themes of his philosophy - the understanding of human individuality as an essential goal of history and the human sciences. Dilthey meant to further such understanding with a comparative psychology, but he never completed it as he went through a transition in which he reconsidered some of his assumptions about the role of psychology and began to develop his

later hermeneutic approach to the human sciences.

3 The formation of the historical world

With his ‘Entstehung der Hermeneutik’ (‘The Rise of Hermeneutics’) in 1900, Dilthey began to sketch out a position which would define his work until his death. While he does not abandon the psychological description of lived experience, Dilthey comes to view its ability to capture the meaning of our life as more limited. Much of the meaning of our experience remains unconscious until it is expressed. Thus the description of the life of the subject cannot be done without the interpretation of its expressed objectifications. Dilthey resumed the task of a Critique of Historical Reason from this hermeneutical perspective, publishing *Der Aufbau der geschichtlichen Welt in den Geisteswissenschaften* (*The Formation of the Historical World in the Human Sciences*) in 1910.

There is a further problem which occasioned Dilthey’s move to hermeneutics and underscores the limitations of description. The descriptions of psychology seem to function primarily on the scientific level of representational consciousness which - however well-integrated - stands apart from the world. How do we deal with prescientific reflexive awareness according to which we are already part of the world? Can description also be applied to its more inclusive life-nexus? Here Dilthey found inspiration in Husserl’s *Logische Untersuchungen* (*Logical Investigations*) and its theory of intentionality. Dilthey had given a seminar on this work in the Winter Semester 1904/5. Husserl in turn visited Dilthey and wrote that this meeting inspired him to occupy himself extensively with the problems of the human sciences (see Husserl, E. §2).

In Dilthey’s ‘Ideen’, understanding was used to describe the connectedness of facts of consciousness. According to his later hermeneutical writings, understanding must clarify these connections as meaning-relations. Since the meaning-relations of our experience and expressions are not necessarily measurable in terms of the framework of the psychic nexus, Dilthey turns to historical life as the ultimate framework for interpretation. Whereas the acquired psychic nexus incorporated the objective sphere into the life of the individual subject, in the *Aufbau* Dilthey becomes equally concerned to conceive the inverse way in which subjects are intentionally related to objective and public spheres. To do so Dilthey appropriates the Hegelian term ‘objective spirit’ as the overall historical context for understanding. He rejects Hegel’s particular definition of objective spirit as the socio-historical stage of the self-realization of absolute spirit in favour of a concept consistent with a reinterpretation of spirit as human activity. ‘Objective spirit’ designates the whole range of human objectifications, whether they be expressions in language and other media meant to communicate, or practices and deeds meant to influence. This objective spirit is at once the embodiment of human thought and action as well as the medium within which they occur. It includes the contexts we share to make interaction possible: not only the sociopolitical institutions originally considered by Hegel, but also the cultural institutions of art, religion and philosophy which he had classified as absolute spirit (see Hegel, G.W.F. §8).

Objective spirit provides the kind of overall framework for Dilthey’s hermeneutics that tradition comes to provide in Gadamer’s hermeneutics. But objective spirit is not as dominant as tradition in Gadamer, for Dilthey articulates it into more specific *Wirkungszusammenhänge* (systems of reciprocal influence), whether they be historical epochs or social and cultural systems. This is relevant to Dilthey’s distinction between elementary and higher understanding. The former orients an expression to the common context of objective spirit. That is, the elementary understanding of a sentence focuses only on what it explicitly asserts and is commonly assumed to mean. Problems concerning the implicit meaning of expressions call for higher understanding, which requires us to refer to more specific systems of reciprocal influence. Thus we attempt to determine any ambiguous expressions in a legal document by considering the particular legal system of the period in which it was drawn up. Only after having exhausted what the appropriate public contexts of expressions can do to clarify their objective meaning, should we turn to the subjective or psychological context. Now psychology is no longer the first of the human sciences, but the last. The highest or last mode of understanding is the *Nacherleben* or re-experiencing of an expression of lived experience. This re-experiencing does not involve reproducing the state of mind of the author. Hermeneutics expects us to understand authors not as they understood themselves, but better.

Although his hermeneutics ultimately focuses on the relation between lived experience, expression, and understanding (*Erlebnis*, *Ausdruck*, *Verstehen*), Dilthey admits that many expressions such as mathematical formulas and handshakes expressing agreement can be understood apart from relating them to lived experience. But when an expression does articulate our lived experience, as in a work of art, it can enrich our understanding of

life in immeasurable ways. This is why Dilthey’s writings on the imagination of artists bear importantly on his theory of interpretation.

4 Anthropological reflection on life and types of worldview

Dilthey’s aesthetic writings play a central role in his philosophy. They not only contribute to his conception of interpretation as it functions in the theory of the human sciences, but they also explicate the way in which we reflect about the meaning of life in everyday existence. There are many levels at which we try to understand what happens in life. Both prescientific anthropological reflection and scientific psychological description contribute to the understanding of order in our lives. Similarly, the categories whereby we establish order in the world are by no means purely scientific, but can in some cases be traced back to the ‘syntactical articulation of language’. Sometimes the same category (for example, Aristotle’s acting and suffering) can receive varying formulations as it functions at the level of ordinary experience (for example, efficacy), of the human sciences (for example, influence), and of the natural sciences (for example, causality). Other categories such as value, purpose and meaning are distinctive of the human sciences. The peculiar fascination of the arts, especially the literary arts, is that they can somehow relate all these levels in the search for order, without, however, producing a conceptual system. Like philosophers and religious thinkers, certain great poets have the capacity to articulate a comprehensive worldview.

One of Dilthey’s last essays was *Die Typen der Weltanschauung und ihre Ausbildung in den metaphysischen Systemen* (*Types of Worldview and their Development in Metaphysical Systems*) (1911). Whereas the kinds of worldview found in art and religion are quite diverse, worldviews in Western philosophy have received a more conceptual, metaphysical formulation that allows them to be distinguished into three main types: naturalism, the idealism of freedom and objective idealism. Naturalism as found in Democritus, Hobbes and others, reduces everything to what can be perceived or determinately cognized and is pluralistic in structure; the idealism of freedom as found in Plato, Kant and others insists on the irreducibility of the will and is dualistic; objective idealism as found in Heraclitus, Leibniz and Hegel affirms reality as the embodiment of a harmonious set of values and is monistic. Each of these metaphysical types of worldview is a perspectival interpretation of reality respectively emphasizing either our cognitive or representational capacities, our volitional ends, or what is felt to be valuable. Despite being totalistic, these types of worldview cannot attain absolute knowledge, according to Dilthey.

Because Dilthey analyses three incommensurable types of worldview that recur, he is often considered a relativist. In his essay ‘Philosophie als strenge Wissenschaft’ (‘Philosophy as a Rigorous Science’), Husserl quotes some passages from this essay that also seem to lead Dilthey down the path of historicism. In one of them, Dilthey uses ‘the development of the historical consciousness’ to question the universal validity of any metaphysical worldview that claims to comprehend conceptually how everything in the world is interconnected. By appealing to historical consciousness, Dilthey is not, as Husserl thinks, making a mere factual claim about the inability of past metaphysical speculative systems to gain universal acceptance. Historical consciousness is for Dilthey a broadening perspective that takes claims out of their actual local contexts and locates them in the sphere of universal history. It is a product of the Enlightenment and could even be considered the counterpart of the transcendental point of view. Indeed, Dilthey’s stance here is analogous to Kant’s in rejecting metaphysical speculation and is no more relativistic or historicist than Kant’s standpoint.

Dilthey’s historical consciousness makes possible a critical analysis of worldviews, and it is this kind of analysis that shows that metaphysical worldviews cannot be scientifically adjudicated. Any effort to provide a comprehensive scientific account of reality would have to synthesize the results of the natural sciences and the human sciences. But ultimately the approaches of these two kinds of science are so different that they cannot in principle be synthesized. Dilthey’s appeal to historical consciousness is thus not at all a challenge to the objective validity of science. It is instead an attempt to preserve the objectivity of scientific *Erkenntnis*. Worldviews, in turn, have their main value for Dilthey as reflective articulations of the meaning of our own life-nexus as given in prescientific *Wissen*.

Diodorus Cronus (late 4th-early 3rd centuries BC)

The most famous member of the Dialectical school, the Greek philosopher Diodorus Cronus maintained various paradoxical theses. He argued that any attempt to divide space, time or matter must end with little regions, periods or bodies that cannot further be divided; hence, he inferred, things cannot be in motion. Diodorus also contributed to the contemporary debate on conditionals: one proposition implies another, he held, if and only if it never has been possible, and is not now possible, to have the former proposition true and the latter proposition false. Diodorus is however most famous for inventing the master argument. The master argument relied on two assumptions: that every past truth is necessary, and that the impossible does not follow from the possible. It concluded, on these assumptions, that no proposition is possible unless it either is true or will be. The master argument was designed to support Diodorus' definition of possibility: a proposition is possible if and only if it either is or will be true. This definition is not exactly tantamount to the fatalist doctrine that all truths are necessary, but it was felt to come too close to fatalism for comfort.

1 Life and reputation

Born in Iasos, in Asia Minor, during the last half of the fourth century BC, Diodorus died around 284 BC. The abusive nickname 'Cronus' ('Old Fogey') he inherited from his teacher Apollonius Cronus. Diodorus was the greatest showman among the Dialecticians (see Dialectical school), a school to which, it is said, his five daughters also belonged. He held that words get their meaning not from nature nor even from convention, but instead from the intention with which they are uttered; and that in consequence none of his words were ambiguous unless uttered with the intention of saying more things than one. His views on meaning he illustrated by giving a daughter the male name 'Theognis', and by naming a slave with the Greek equivalent of 'In fact however'. He helped refine various already current paradoxes such as the liar paradox ('What I am saying is false'), the veiled paradox ('You don't know who the man behind the veil is. He is your father. So you don't know who your father is') and the paradox of the Sorites (which in Diodorus' hands became 'If two in a trio of atoms are in motion, then the trio are predominantly in motion; if the trio are predominantly in motion, then a quartet to which that trio belong are also predominantly in motion; and so on; so a myriad of atoms will be predominantly in motion, even if only two of them are actually moving'). Diodorus' most celebrated contributions were his arguments against change, his theory of logical consequence and the views on modality which he defended with his master argument. It was said that 'even the crows on the roof-tops caw' about the issues Diodorus raised; and conversation about the master argument was a notoriously effective way of blighting dinner parties. In modern times, the master argument has become the subject of a massive literature, much of it highly speculative.

2 Atomism and change

Diodorus held that all things consist of 'minimal and partless bodies' so small as to be indivisible, but big enough for there to be only finitely many of them in any finitely sized body. He held similar views about time and space: any larger stretch of time may be divided into short periods, each of length greater than zero but with no smaller parts into which it can be divided; and each finite space consists of finitely many indivisible volumes.

Diodorus concluded that nothing is ever moving. Sextus Empiricus gives the fullest single report of Diodorus' many arguments on these matters:

> If something is moving, it is moving now. If it is moving now, it is moving in the present time. If it is moving in the present time, it is moving in a partless time. For if the present time is divided, it will be divided completely into the past and future, and so will no longer be present. If something is moving in a partless time, it traverses partless places. If it traverses partless places, it is not moving. For when it is in the first partless place, it is not moving; for it is still in the first partless place. And when it is in the second partless place, again it is not moving, but has moved. So nothing is moving.
>
> (*Against the Professors* X 119-20)

Although Diodorus denies that things move, he concedes that they are not now where they were, and that they therefore have moved. If we wonder how a thing can have moved without ever moving, Diodorus points out that Helen had three husbands, even though the present-tensed 'Helen has three husbands' was never true; for her

husbands were successive, not simultaneous.

3 Conditionals and consequence

It was widely agreed that the relation between antecedent and consequent in a true conditional is the same as that between premises and conclusion in a valid argument: the conclusion (or consequent) was said to ‘follow from’ the premises (or antecedent). This was unfortunate. It implies that in an argument like:

It is day.
If it is day, it is light.
So, it is light.

the conditional premise is either false or redundant. The parties to the unfortunate agreement that these two relations are identical did however dispute about what the single relation was (see Philo the Dialectician §2).

Diodorus was party to the agreement, and also to the dispute. He declared that one proposition follows from another if and only if it neither was nor is possible for the former to be false while the latter is true.

An immediate consequence of Diodorus’ definition is that if one proposition now follows from another, then it has always done so. This consequence is a defect if Diodorus’ definition is taken as an account of which conditionals are true. For by holding out my right arm I can make true a previously false conditional: ‘If I hold out my left arm, both my arms will be held out’. This consequence is however a virtue if Diodorus’ definition is taken as an account of which arguments are valid. For it would be astonishing if a previously invalid argument should become valid.

On Diodorus’ definition, everything follows from a proposition that is and always has been impossible; and a proposition that is and always has been necessary follows from everything. Diodorus’ atomism was invoked to give a piquant illustration of both points simultaneously: on Diodorus’ account, ‘There are minimal and partless bodies’ follows from its own negation, ‘There are no minimal and partless bodies’.

Diodorus’ explanation of following can be explained further. The result is: one proposition follows from another if and only if there is no time when the former is false and the latter is true. This result is reached by applying, to Diodorus’ original definition of following, his definition of possibility.

4 The definition of possibility

Diodorus defined the possible as what is or will be true (for example, it is possible for me to be in Corinth if and only if I am or will be there), and the necessary as what, being true, will never be false. Diodorus therefore disagreed both with the Aristotelian idea that the necessary is what is true at every time, and with the Megaric idea that the possible is what is true now (see Megarian school).

One curious consequence concerns change of modalities. On Diodorus’ definitions, what was once contingent can become either necessary or impossible. The reverse change cannot take place: once something is either necessary or impossible it remains so for ever. As time passes, previously open possibilities therefore get closed off. Moreover, the only way a previously open possibility can get closed off is by being actualized: if something once was possible but is no longer so, then it has been actually true in the meantime.

A second curious consequence concerns ‘future contingents’, propositions of the form ‘So-and-so will happen’ that are neither necessary nor impossible. Suppose that ‘Adam will sin’ is such a proposition. If ‘Adam will sin’ is not impossible, then, on Diodorus’ definition, it either is true now or will be true in the future; either way, Adam will sin. If ‘Adam will sin’ is not necessary, then, on Diodorus’ definition, it either is or will be false. But since Adam will sin, the first alternative can be eliminated. Hence ‘Adam will sin’ will be false at some time in the future. Moreover, once such a proposition is false, it will remain false for ever thereafter. Hence, on Diodorus’ definition, ‘Adam will sin’ will become and remain impossible. This reasoning is generally applicable: on Diodorus’ definition, each future contingent is now true and will eventually become permanently impossible.

A third curious consequence concerns past necessities. If a proposition has been true, then it always will have been so. By Diodorus’ definition, past truths are therefore necessary. This applies only to simple past tensed truths, like ‘Diodorus was born in Iasos’. The more complex truth ‘Diodorus’ fragments have never yet been properly edited’ is contingent if his fragments will be properly edited in future. And the metric truth ‘Diodorus was born nearly 25

centuries ago' can also be false, for it will be.

Why should Diodorus' definition be accepted? It is obvious enough that if something is or will be true, then it is possible. More controversial is the converse, that if something is possible, then it is or will be true. To establish the converse, Diodorus devised the master argument.

5 The master argument

According to Epictetus:

> The master argument seems to have been put forward from some such starting points as these. There is a mutual inconsistency of these three propositions with one another:
>
> Every past truth is necessary;
>
> The impossible does not follow from the possible;
>
> Something is possible which neither is true nor will be.
>
> Diodorus saw this inconsistency and used the plausibility of the first two propositions to establish that nothing is possible which neither is true nor will be.

(*Discourses* II 19.1)

The word translated 'past' is the most general term for verbs in any of Greek's various past tenses. Hence Diodorus' first premise presumably means that each true proposition in a past tense is necessarily true. This interpretation is that of Chrysippus, who accepted the first premise (Epictetus, *Discourses* II 19.2-5) and who defended it on the grounds that past truths cannot change from true to false (Cicero, *On Fate* 14): Chrysippus' reasoning is entirely cogent if by 'past truth' we mean only simple past tensed truths, like 'Diodorus was born in Iasos'.

How did Diodorus reason from his first two premises to the negation of the third? We learn of the first two premises because they were disputed by Stoics, who rejected Diodorus' conclusion but who could find nothing other than these two premises to contest (see Cleanthes). Hence our reconstruction should not make obvious use of other premises more likely to be contested by the Stoics than these first two. Here is one reconstruction to meet this standard.

Let us take the proposition 'Diodorus snores'. From this proposition, it follows that 'Diodorus snores' never was at any past time going to be false for ever thereafter. Hence, if this proposition is possible, then it is possible also that 'Diodorus snores' never was at any past time going to be false for ever thereafter (for the impossible does not follow from the possible). If however our proposition now is and always will be false, then 'Diodorus snores' was at some past time going to be false for ever thereafter; indeed, it is necessary that 'Diodorus snores' was at some past time going to be false for ever thereafter (for every past truth is necessary). Hence if the same proposition is and always will be false but is nevertheless possible, we have a contradiction: that the proposition will always be false has necessarily been so at some time, and also has possibly never been so.

Diogenes Laertius (*c.* AD 300-50)

Diogenes Laertius is the author of a famous work entitled Lives of the Philosophers consisting of nearly one hundred accounts of individual philosophers. These contain mainly biographical information, but sometimes also include doctrinal summaries. The work is extremely valuable because it preserves much information on Greek philosophers from sources now lost.

Diogenes Laertius is the author of the only work to come down to us from antiquity that gives a comprehensive account of the Greek philosophical tradition. It consists of ten books, which contain eighty-four accounts of individual Greek philosophers, varying in length from an entire book to a few lines. Very little is known about the author. A disputed text (IX 109) suggests that his home town was Nicaea in Bithynia (not far from Byzantium). This provincial location might explain the somewhat dated quality of his erudition. Diogenes scarcely mentions philosophers of the Roman period except for a list of Sceptics at IX 116. The last-named of these is a pupil of Sextus Empiricus, which indicates that he wrote the book no earlier than the first half of the third century AD. Diogenes himself does not belong to any philosophical school, but does appear to have sympathy for the philosophy of Epicurus (X 29).

An older title of Diogenes' work, known since the Middle Ages simply as *Lives of the Philosophers*, gives a more accurate indication of its content: *Lives and Maxims of Those who Gained Fame in Philosophy and the Doctrines of Each School*. The overall structure of the work is determined by the theory of successions in Greek philosophical historiography (see Doxography), as the following summary shows:

Book I the seven sages, including Thales;
Book II the Ionian succession, including Anaximander, Anaxagoras, Socrates and the Socratics;
Book III Plato;
Book IV Plato's successors in the Academy;
Book V Aristotle and his successors in the Lyceum;
Book VI Antisthenes, Diogenes and the Cynic philosophers;
Book VII Zeno and the Stoic philosophers (some twenty chapters have gone missing at the end);
Book VIII the Italian succession, headed by Pythagoras and Empedocles;
Book IX the 'scattered' philosophers, including Heraclitus, Parmenides and Democritus;
Book X Epicurus.

Only one woman philosopher receives a separate chapter: Hipparchia the Cynic (VI 96-8).

The work is in an unfinished state. Individual chapters or 'biographies' contain a remarkable variety of material, giving the work an uneven and compilatory quality. Doctrines are only presented in detail when the chapter deals with the founder of a school (for example, the extremely valuable doxography on the Stoics in Book VII). A typical chapter includes the origin of the philosopher and who his teachers were, the date when he flourished (*akmē*), anecdotes illustrating his life, maxims, lists of works (extremely valuable), other documents such as wills and letters (the latter usually fictitious), an epigram by the author on the philosopher's death, and a list of other persons with the same name. Diogenes does not write a history of philosophy in the modern sense. He combines biographical and doctrinal material because he is convinced, like most writers on philosophy in antiquity, that there is a intrinsic relation between the *bios* (life) and the *logos* (doctrine) of every philosopher.

The value of the information supplied by Diogenes is entirely dependent on the quality of his sources. The nature and extent of these has long been the subject of debate. It is now thought that he has excerpted and stitched together material from widely scattered sources. These date mainly from the Hellenistic period, and include many important works in the historiography of ancient philosophy which are no longer extant. Since the Byzantine period Diogenes' work has been extensively used. No other work provides us with so much information on ancient philosophers. Despite its undeniable mediocrity, it is truly priceless.

Diogenes of Apollonia (5th century BC)

Diogenes was the last of the early Greek physicists. He claimed that interactions between things would be impossible unless all were forms of one basic substance. Adapting ideas of Anaximenes and Anaxagoras, he identified the basic substance as air, which in its optimal form possesses intelligence and thereby controls the universe at large and animal life in particular. Diogenes worked out a detailed psychology and physiology, explaining sense perception as an exercise of intelligence due to interaction between air in the region of the brain and atmospheric air. This theory was mocked by Aristophanes, but influenced various Hippocratic writings.

1 Life and work

Almost nothing is known of Diogenes' life. His birthplace Apollonia was probably the Milesian colony of that name on the Black Sea. Diogenes Laertius (IX 57) dates him to the same period as Anaxagoras (500-428 BC). Aristophanes' allusion to his ideas (*Clouds* 227-33) and Theophrastus' statement that he was pretty much the last of the Presocratics (A5) suggest someone younger. Simplicius attributes the surviving fragments to a general work on nature (A4), but the sequence of topics would seem to point to another of the treatises by Diogenes - *On the Nature of Man* - as their probable source.

Diogenes is elsewhere credited like the atomists with belief in an infinite number of worlds, and with a cosmogony and account of the earth and the heavenly bodies which largely recapitulate Anaxagoras' theories (A1, A6, A12) (see Anaxagoras §4). Indeed, Theophrastus explicitly represented him as drawing eclectically from these two major fifth-century systems (A5). But the work from which Simplicius quotes evidently had a quite different theme. It began with metaphysical argument for the fundamental identity of all physical things (fr. 2). Then, consequent upon proofs that the universe is permeated with intelligence (frs 3 and 4), it contended that the seat of intelligence is air, which is a single substance, despite variations in temperature, moisture and mobility etc. (fr. 5). Simplicius assures us that this substance is the eternal imperishable body whose existence was derived a priori in the opening argument (frs 7 and 8).

There followed a sequence of proofs designed to substantiate the dependence of animal life and intelligence upon air. Simplicius mentions demonstrations that sperm is aerated and that acts of intelligence occur when air via blood takes possession of the whole body. He refers to an anatomy of the human veins, which is preserved more or less verbatim by Aristotle (*History of Animals* III 2, see Diogenes fr. 6). Diogenes probably gave his account of sense perception, extensively reported by Theophrastus (A19), at this point in the book, along with discussions of physiological phenomena like sleep and digestion.

These detailed explanations appear to have constituted the real focus of the work. Its structure is just what one might expect of a fifth-century book 'on the nature of man': Polybus, author of the Hippocratic treatise bearing this title, complains of the way some writers on human physiology preface their accounts with grandiose claims, supported by meaningless proofs, about a single basic substance.

2 Monism

Ancient and modern historians of philosophy alike see Diogenes' theory as reviving the system of Anaximenes a century earlier (see Anaximenes §1). But it is a revival informed by reflection on more recent philosophy. Thus the argument for Monism found in fragment 2 has clear affinities with theses of Anaxagoras and Democritus, although Democritus may depend on Diogenes; there are also verbal echoes of Melissus and Empedocles. Diogenes proposes that two objects cannot mix with or benefit or harm each other, nor can one grow or be born from another, unless they are really - 'in their nature' - the same. Since he assumes that the four elements all do interact with one another, he concludes that all of them, and therefore all things whatsoever, are forms of the same basic substance. Diogenes' monism therefore allows for a world of variety and change. Nor does he acknowledge any need to rebut Melissus' proofs of the logical impossibility of alteration, even if the wording of fragment 2 betrays his familiarity with them.

Diogenes' arguments that there is 'much intelligence' in the basic substance recall Heraclitus as well as Anaxagoras. He appeals principally to the optimal disposition of day and night and the seasons, but also to the role of soul and intelligence in sustaining animal life (frs 3 and 4). Yet this is only preparatory to enunciation of his

main thesis: the identification of air as what possesses intelligence. Once again Diogenes echoes Anaxagoras (fr. 12: see Anaxagoras §4), but this time to subvert his insistence that mind (*nous*) is something pure from admixture with any other kind of substance. For Diogenes it is not mind, but the air that is its physical seat which permeates all things and thereby organizes and controls them. It is accordingly air that is to be regarded as what is strong and eternal and 'knowing many things' (fr. 8), and as thereby deserving ascription of the divinity Anaxagoras effectively predicated of mind. Mind is in fact an attribute, not a substance at all. Hence no doubt the substitution of *noēsis*, 'intelligence', for Anaxagoras' *nous*.

Only air in a particular state has the power of intelligence; namely, when hotter than atmospheric air, but cooler than that in the vicinity of the sun (fr. 5). The surviving fragments say nothing of how air can take the form of, for example, earth or water (although the doxography speaks of compression; A1, A6). We might wonder why evidence that air pervades and controls everything should suggest that it is the basic substance. No doubt the underlying thought is simply that no substance *could* be dominant without being basic.

3 Psychology and physiology

If Diogenes conceived his chief general contribution to philosophy as rescuing Anaxagorean metaphysics from dualism, his work in psychology and physiology was, as noted, more influential. Diogenes' systematic treatment of these topics challenges comparison with those of Anaxagoras and Empedocles. Following the argument given in fragment 2, he made sense perception a product of interaction between air within and air without (Theophrastus, *On the Senses* 39-45). His exposition began unusually but understandably with the best cases for his theory: smell and then hearing. A weaker explanation is provided for sight and taste however. Diogenes' fanciful analysis of the vascular system allowed him to argue that air was conveyed by blood throughout the body to various destinations, including notably the head. Following Alcmaeon he conceived of the brain as the principal seat of sensations, which were apparently construed as functions of intelligence: Diogenes observed that when we have our minds on other things, we neither see nor hear. In general, the finer the air within and the more delicate the passages through which it is conveyed, the more acute the associated perceptions.

This explanatory scheme was applied to a great variety of phenomena. To take just one, pleasure is viewed as the result of efficient mixture of air and blood in the veins permeating the whole body. Many undesirable conditions are put down to the effect of moisture or *ikmas*. Evidently a key Diogenean notion, this was used to explain such phenomena as magnetism and the flooding of the Nile (A18, A33). Its action upon internal air inhibits intelligence, as manifested in sleep and drunkenness, and may also (to Aristophanes' amusement) be evidenced in animals which breathe air close to the ground.

Diogenes of Oenoanda (*c.* 2nd century AD)

The Epicurean philosopher Diogenes came from the Greek town Oenoanda in Lycia (Turkey). He is known exclusively for his massive philosophical inscription, erected in a colonnade there. Its remains contain sayings of Epicurus, plus Diogenes' own writings, mainly on physics and ethics. His Epicureanism is largely traditional, but possible innovations include talk of a future Epicurean golden age.

Diogenes is known for the inscription he erected in a colonnade in the town of Oenoanda, Lycia (Turkey), his birthplace. Most probably the inscription belongs to the second century AD. Diogenes informs the reader that he was already old and sick when he set up the inscription. We also learn that he was in contact with Epicurean friends in Athens, Chalcis, Thebes and Rhodes. The fact that he could afford to set up this enormous inscription in a public place testifies that he was a wealthy and influential man in Oenoanda.

Since 1884, 212 blocks or fragments have been discovered. The inscription probably covered a wall about 80 metres in length in the town's south stoa or colonnade, on the so-called esplanade. The text was arranged in either five or seven courses, carrying treatises on ethics, physics and old age. The ethics section (frs 28-61) was the lowest inscribed course and was underwritten by a course of maxims of Epicurus. They support Diogenes' argument, and are clearly meant to establish its Epicurean authenticity. The physics treatise, on the next course, starts with an introduction to the whole inscription. Higher courses carried letters of Diogenes (to his friends Antipater, Dionysius, Carus and Menneas) and his maxims, as well as letters attributed to Epicurus. Above stood Diogenes' treatise *On Old Age* (frs 137-79). Each section of the text looks like an opened papyrus scroll.

Diogenes wants the physics part to be read first, and at the beginning he announces the aim of his inscription: to help those who are 'well-constituted'. Like Epicurus he regards philosophy as a therapy, and intends to offer his philosophy as a medicine not only for his fellow citizens but also for foreigners: they are all citizens of one country, the world. The inscription, closely following traditional Epicureanism, attests its author's humanity and cosmopolitanism.

The physics and ethics treatises deal mainly with standard Epicurean topics. However, one remarkable fragment of the ethics treatise describes an Epicurean golden age, a future in which justice and friendship will render the protection of citizens by institutions unnecessary (fr. 56).

In the treatise on old age (frs 137-79) Diogenes addresses young readers and repudiates their negativity about old age, in which, he maintains, the mind remains active. Homer shows that old men are excellent speakers. If slow like the elephant, the old also resemble it in intelligence. The absence of sensual desires is not a disadvantage. Poverty is more valuable than wealth.

Among the letters and maxims, the letter to Antipater (imitating Epicurus' *Letter to Pythocles* in form and content; see Epicurus §2) sheds some light on Diogenes' life and his contacts with Epicurean friends in Greece. Philosophically, it deals with the infinite number of worlds. Other of Diogenes' fragments contain the remains of a letter to Dionysius (and Carus?) whose topics were epistemological, ethical and biographical. It speaks of Epicurus 'the herald who brought you complete salvation' (fr. 73 III 13), and we learn of Epicurus' narrow escape from death after a shipwreck. Most important are the fragments of a letter by Epicurus to his mother, which deals with visions of absent persons, the author's happiness and the fear of death, along with a plea not to send money any more since the author has sufficient (frs 125-6).

Diogenes of Sinope (412/403-324/321 BC)

*Diogenes of Sinope was considered, along with Antisthenes, the founder of Cynicism. His nickname 'Cynic', literally 'doglike', reflects the highly unconventional lifestyle he lived and advocated. Radically re-evaluating mankind's relation to both nature and civilization, Diogenes redefined the individual's freedom and self-sufficiency, advocating a training (*askēsis*) for achieving both.*

Although a historical figure, Diogenes quickly became a literary character - probably in his own lost works, certainly in those of others. Hence his life, lost writings and oral teachings are intertwined in a complex tradition comprising: (1) a biographical strand transmitted by Diogenes Laertius - itself a collage of literary and oral traditions about Diogenes; (2) the more overtly literary representations by writers such as Lucian and Dio Chrysostom (*Discourses*). Contemporary evidence for Diogenes is virtually nil.

Critical assessment of the biographical tradition is more than usually important in Diogenes' case, since his thought is transmitted to us primarily in the form of pointed anecdotes and aphorisms (*chreiai*). Diogenes was exiled from Sinope (on the southern coast of the Black Sea) for defacing the city's coins. 'Defacing the currency' was to become a central metaphor for the Cynics' critique of the tradition - driving out the counterfeit coin of conventional wisdom to make room for the authentic Cynic life lived 'according to nature'. Surprisingly, numismatic evidence discovered in the twentieth century appears to confirm the story of Diogenes' exile, but that may be the only trustworthy part of the biography. The tradition also claims that Diogenes (1) studied with Antisthenes, (2) discovered his vocation ('defacing the currency') by consulting an oracle and (3) was sold into slavery and spent the rest of his life as a private tutor to his master's children. Claim (1) may be chronologically impossible, and was perhaps fabricated by Stoics eager to give their school a Socratic pedigree via the Cynics. Claim (2) is suspiciously reminiscent of stories told of Socrates and of Zeno of Citium. Claim (3) conflicts with the tradition that Diogenes grew old spending his summers in Corinth and winters in Athens living in his *pithos*, a large wine-jar. In all probability, both (2) and (3) are based on literary works by or about Diogenes that were later treated biographically.

Similarly, there are several conflicting versions of Diogenes' literary activity. Two authorities denied that Diogenes had left anything in writing, yet we have two lists of works attributed to him. The first consists of thirteen dialogues (including a *Republic*), some epistles and seven tragedies. A second list, probably of Stoic origin, consists of twelve dialogues (eight of which are absent from the first list) and some letters and sayings (*chreiai*), thus implicitly denying the authenticity of Diogenes' *Republic* and of his tragedies.

Diogenes' philosophical significance was a product of the manifold traditions purporting to represent him as much as it was of the facts of his life, of which we know few. Diogenes' unconditional pursuit of happiness in the face of exile and poverty led him to challenge the most fundamental ideas and taboos of Greek civilization and to valorize nature as a source of moral insight greater than that of custom or of the existing philosophical schools. The consequences of his experiment were remarkable and lasting, not only for philosophy - Stoicism and Epicureanism emerge in the philosophical context Diogenes helped to create - but for the literary and social traditions that antiquity transmitted to Europe.

Discourse semantics

Discourse and its interpretation have interested philosophers since ancient times, and have been studied in different areas of philosophy such as rhetoric, the philosophy of language and the philosophy of literature. Discourse has attracted interest from philosophers working in the continental tradition, and it received considerable attention in the 1980s from analytic philosophers, philosophers of language, linguists, cognitive scientists and computer scientists; within these fields a formal, logical analysis of discourse interpretation, or discourse semantics, has emerged.

Discourse semantics arose in an attempt to solve certain problems that affected formal theories of meaning for single sentences. These problems had to do with the interpretation of pronouns and other 'anaphoric' elements in language. A detailed examination of the data showed that the meaning of an individual sentence in a discourse could depend upon information given by previous sentences in the discourse. To analyse this dependence, discourse semantics developed a formal analysis of a discourse context and of the interaction between the meaning of a sentence and the discourse context in which it is to be interpreted. The essential idea of discourse semantics is that the meaning of a sentence is a relation between contexts. The 'input' discourse context furnishes the information needed to interpret the anaphoric elements in the sentence; the information conveyed by the sentence when added to the input context yields a new, or 'output', discourse context that can serve to interpret the next sentence in the discourse.

1 Static semantics for discourse and its difficulties

To understand the development of discourse semantics, one must look at the problems that motivated its development. To do this, one must know something about the interpretation of the constituents of discourse - the constituent sentences and their constituent phrases as treated in standard formal semantics. In the 1960s, Richard Montague developed a very influential framework, Montague Grammar, for analysing how the meaning of a complex expression depends on the meanings of its constituents (see Compositionality; Possible worlds; Semantics). One might think that there is nothing more to the interpretation of a discourse than simply building up the meanings of its constituent sentences and then combining them. But once a clear and precise proposal for the semantics of sentences was given by Montague Grammar, several problems emerged that showed that the interpretation of discourse would not be so simple. There are two related phenomena in semantics that cause difficulty for Montague Grammar, namely pronominal anaphora and temporal anaphora, and these have spurred advances in the analysis of discourse.

Pronominal anaphora. One problem for the Montague Grammar approach to discourse is the interpretation of anaphoric pronouns. Pronominal anaphora occurs when a pronoun refers back to some word or phrase in the preceding discourse. In the discourses below, the anaphoric pronouns 'he' and 'it' refer back respectively to a 'farmer' and a 'donkey'.

(1) A farmer owns a donkey and he beats it.
(2) A farmer owns a donkey. He beats it.
(3) If a farmer owns a donkey, he beats it.

In semantics the meaning of a discourse like (1) can be given by a formula of some logical language with a clear model-theoretic interpretation - this formula is known as the logical form of the sentence. Montague Grammar uses the language of intensional, higher-order logic, but for our purposes the only thing we need to know about this language is that indefinite noun phrases like 'a farmer' are translated as existential quantifiers and pronouns are translated as bound variables. Thus, a sentence such as (1) has the translation:

$$\exists x \exists y(\text{farmer}(x)\ \&\ \text{donkey}(y)\ \&\ \text{owns}(x,\ y)\ \&\ \text{beats}(x,\ y))$$

The first problem for Montague Grammar is that since it gives the meaning of a discourse sentence by sentence, it is unclear how to connect the pronouns in the second sentence of (2) with the existential quantifiers that bind them in the first sentence. Another problem emerges with the attempt to treat (3), which is an example of the 'donkey sentence problem' originally discovered by Geach (1963). The meaning of (3) is captured by the formula:

$$\forall x \forall y((\text{farmer}(x) \ \& \ \text{donkey}(y) \ \& \ \text{owns}(x,\ y)) \ \rightarrow \ (\text{beats}(x,\ y))$$

But Montague Grammar has no uniform translation of the indefinite determiner *a* that yields a correct treatment of (1) and (3) satisfactorily; it does not provide any explanation of why the translation of indefinites is context-sensitive in this way, nor does it handle inter-sentential anaphora (see Anaphora).

Temporal structure of discourse. Observations by Barbara Partee and people working on the analysis of French tense in discourse first brought attention to a facet of the meaning of tenses that was missing from the best analyses of tense of the day. Those analyses took tenses to be temporal operators of the sort found in tense logic. In a French discourse like:

(4) Pierre entra dans le salon. Il s'assit sur la banquette. Il s'endorma.
(Pierre entered the room. He sat down on the sofa. He fell asleep.)

the three events introduced (Pierre's entering, his sitting down, and his falling asleep) all occur in the past if (4) is true. This much the analyses of tense were able to capture. But they miss a crucial generalization about texts like (4). The events described there are portrayed as occurring not only in the past but also in a definite sequence - that in which they are introduced in the discourse. We naturally understand the story as telling us that Pierre's entering the room occurred prior to his sitting down which in turn occurred prior to his falling asleep. On the operator view of tenses, a past-tensed sentence of the (logical) form $P\varphi$ is true just if φ holds for some time prior to the moment of speech; this view is incapable of capturing the contextual sensitivity shown in (4). Similarly incapable are views on which verbs are treated as predicates of events and the past tense introduces a relation of 'earlier than' between the event and the moment of speech (see Tense and temporal logic).

2 Dynamic semantics for discourse

Motivated by the problems with the interpretation of pronouns in discourse, Hans Kamp (1981) and Irene Heim (1982) independently proposed not only a solution to the interpretation of anaphoric elements but a new way of looking at discourse semantics. They redefined the semantic contributions in a discourse of a sentence and its constituents. In Montague Grammar, among other accounts of discourse interpretation, the contribution of a sentence is a proposition, or, formally, a set of possible worlds in which the sentence is true. Such a proposition contributes to the content of a discourse in a simple way: the meaning of a discourse is just the intersection of all the propositions that are the meanings of the discourse's constituent sentences. For Kamp and Heim, a sentence *S* when interpreted in a discourse *D* no longer simply yields a set of worlds; *S* may also yield a set of discourse entities or 'discourse referents' to which elements of subsequent discourse may refer. This approach came to dominate semantics in linguistics during the 1980s and 1990s. What follows develops Kamp's approach to discourse semantics, known as 'Discourse Representation Theory' or DRT.

DRT assigns a truth-conditional meaning to a natural language discourse in two steps: the 'DRS construction procedure' and the 'correctness definition'. The first step is to construct a representation of the content of the discourse (known as a 'Discourse Representation Structure' or DRS). The ontological status of a DRS has been subject to some debate: some view it as a partial model of the discourse, others view it merely as an alternative logical form for English, still others as some sort of conceptual structure. Nevertheless, the structure of a DRS is precisely defined. It consists of a pair of sets: (1) a set, or 'universe', of discourse referents, and (2) a set of 'conditions'. Discourse referents are analogous to the domain of a partial model - they are objects talked about in the discourse - while conditions are property ascriptions to these discourse individuals. The technical definition of a DRS and DRS condition is given through a doubly recursive definition. In thinking of DRSs as partial models, DRSs as abstract structures should be distinguished from the language used to describe them. The DRS language uses a box notation - the upper part of the box lists the discourse referents in the universe of the DRS, while the bottom part of the box describes the conditions. Kamp's notation is in fact reminiscent of Peirce's existential graphs. For instance, the DRS for 'a farmer owns a donkey' is given in (K1); it tells us that the discourse speaks of two entities, one a farmer (*x*), one a donkey (*y*), and that, according to the discourse, the farmer owns the donkey.

(K1)

$$\begin{array}{|c|}\hline x \quad y \\ \hline \text{farmer}(x) \\ \text{donkey}(y) \\ \text{owns}(x,y) \\ \hline \end{array}$$

While Kamp develops a top-down approach to DRS construction, Wada and Asher (1986), Zeevat (1989) and Asher (1993) develop a construction procedure whereby each lexical element contributes some sort of DR-theoretic structure. These then combine following the syntactic structure of the sentence to produce the DRS for the sentence in a manner that is in the tradition of compositional Montague semantics. Noun phrases like ‘a farmer’ or ‘a donkey’ introduce a novel discourse referent into the DRS as well as a condition on that discourse referent; verbs introduce conditions on the discourse referents introduced by the noun phrases that are their syntactic arguments. Anaphoric pronouns, following the original Kamp treatment of DRT (see Kamp 1981), are treated as bound variables; they introduce new occurrences of discourse referents that have been introduced by noun phrases in antecedent discourse.

The construction of a DRS for a discourse proceeds incrementally, sentence by sentence, exploiting the syntactic parse of each sentence, and building a DRS for the discourse as a whole from DRSs for each constituent sentence. More precisely, if $\mathbf{K}_m$ is the DRS derived from the first *m* sentences and K_{m+1} is the DRS derived from the $m+1$st sentence, then the DRS for the discourse of $m+1$ sentences is just the DRS that combines the universes of $\mathbf{K_m}$ and K_{m+1} and their condition sets:

$$\langle(\mathrm{U}_{\mathbf{K}_m} \cup \mathrm{U}_{K_{m+1}}),\ (\mathrm{Con}_{\mathbf{K}_m} \cup \mathrm{Con}_{K_{m+1}})\rangle$$

So in constructing a DRS for (2), for instance, we would add to the DRS in (K1) simply the condition ‘ $\text{beats}(x,\ y)$’ to get a correct representation for (2):

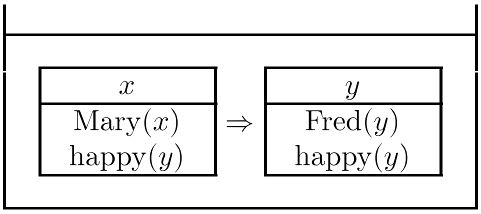
(K2)

$$\begin{array}{|c|}\hline x \quad y \\ \hline \text{farmer}(x) \\ \text{donkey}(y) \\ \text{owns}(x,y) \\ \text{beats}(x,y) \\ \hline \end{array}$$

Let us now briefly look at DRT’s treatment of sentence (3) given in §1. We use the same analysis of indefinite noun phrases and pronouns as introduced above, together with construction procedures for conditionals and universal quantifiers (such as the quantifier expressed by ‘every farmer’). Both constructions introduce what is known as a ‘complex condition’ in a DRS; complex conditions consist of DRSs as arguments to some operator. For instance, ‘if…, then… ’ introduces the following relation on DRSs, where *P* and *Q* are variables for DRSs.

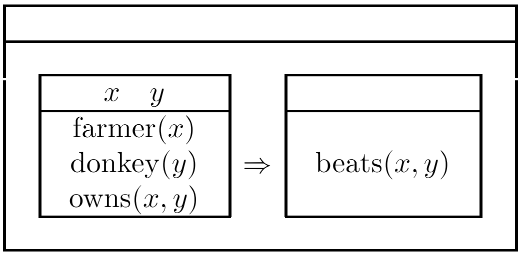
$$\lambda P \lambda Q \quad \begin{array}{|c|}\hline \\ \hline P \quad \Rightarrow \quad Q \\ \hline \end{array}$$

So when we have two clauses linked by ‘if…, then… ’, the first clause gives us a DRS bound by *P*, while the second gives us a DRS which replaces *Q*. For example, ‘if Mary is happy, then Fred is happy’ would yield the following DRS:



If we choose the right discourse referents for the pronouns ‘he’ and ‘it’, we get the right DR-theoretic translation for (3) in a uniform way from the treatment of the indefinite noun phrase and pronouns:

(K3)



Several forms of complex conditions have been proposed in DRT to handle various connectives and quantifiers. Most prevalent are those of the form $K \Rightarrow K'$ used to represent sentences that contain a conditional or universal quantifier, and those of the form $\neg K$ which result from processing sentences in which a verbal or sentence-level negation occurs.

In order to understand what these complex conditions mean we must look at the second component of DRT, the correctness definition. The correctness definition tells us what conditions must obtain in order for a DRS, thought of as a partial model, to be properly embedded in a Tarskian model of the sort familiar from first-order logic (see Model theory). If the DRS for a discourse can be properly embedded in a model *M*, then we say that the discourse is true in *M*. A ‘DRS model’ is a pair <*D*, *I*> where *D* is a non-empty set (a domain of individuals) and *I* is a function that assigns *n*-tuples from D^n to atomic *n*-ary conditions of DRSs. Atomic conditions are those conditions that are derived from natural-language nouns, verbs and some adjectives - the sort that are contained in the DRSs for (1) and (2). A DRS *K* is properly embedded in a DRS model *M* if and only if there is a function *f* from the universe of *K* into the universe of *M* such that all the conditions of *K* are satisfied in *M*. What we have to do now is to define satisfaction of a condition in *K*. Intuitively the idea is simple: for a condition in the DRS to be satisfied in a model, there must be a mapping or embedding of the universe of *K* in the universe of *M* such that the objects $f(x_1),\ldots, f(x_n)$ bear the relation that the DRS condition predicates of $x_1,\ldots, x_n$. For an atomic DRS condition of the form $\Psi(\alpha_1, \ldots, \alpha_n)$, where $\alpha_1, \ldots, \alpha_n$ are discourse referents, $\Psi(\alpha_1, \ldots, \alpha_n)$ is satisfied in a DRS model *M* relative to an embedding function *f* if and only if $\langle f(\alpha_1), \ldots, f(\alpha_n)\rangle$ is an element of the interpretation of Ψ in *M*. A complex condition of the form $K \Rightarrow K'$ is satisfied in a DRS model *M* relative to an embedding function *f* if and only if for every function *g* that extends *f* to a proper embedding of *K* there is an extension *h* of *g* that is a proper embedding of K'. A complex condition of the form $\neg K$ is satisfied in a DRS model *M* relative to an embedding function *f* if and only if there is no function *g* that extends *f* to a proper embedding of *K*. Intuitively, we see how the interpretation of these DRS conditions captures the definition of a material conditional, a universal quantifier and negation. Technically we have a simultaneous recursive definition of proper embedding of a DRS in a model and of the satisfaction of a DRS condition with respect to a model. (For details see Kamp and Reyle 1993.)

In applying this definition of truth to (K3), we get the intuitively right truth-conditions for the sentence: for every pair of objects such that one is a farmer and the other is a donkey and the farmer owns the donkey, the farmer beats the donkey. These truth-conditions are the same as those for the universally quantified sentence, ‘every farmer who owns a donkey beats it’. While some problems in the interpretation of pronouns have been uncovered in further studies on anaphora in a dynamic semantic setting, the dynamic semantic approach represents a considerable advance over Montague Grammar’s approach to the interpretation of pronouns in discourse.

DRT and temporal anaphora. Following Davidson (1967), DRT takes verbs to introduce conditions on

eventualities (events or states) (see Davidson, D. §2). DRT postulates a complex algorithm that serves to connect by means of temporal relations the eventuality introduced by the main verb of a sentence with the eventualities already present in the DRS built up from previous discourse. In declarative form, we formulate the results of the algorithm as follows. If α and β are two sentences that follow one after another in the discourse and both introduce eventualities with a verb in the *passé simple*, we have (where $<$ is the 'earlier than' relation):

$$\mathrm{PS}(\alpha)\ \&\ \mathrm{PS}(\beta) \rightarrow \mathrm{e}_\alpha < \mathrm{e}_\beta$$

If past tense also implies that the event described by the verb occurs prior to the speech time, this rule in effect predicts just the right temporal interpretation of discourse (4). The complex DRS construction procedure has been applied to basic tense forms of French and English (see Kamp and Reyle 1993 for an extensive discussion and bibliography).

Limitations of dynamic semantics. DRT makes an important contribution to our understanding of how the discourse context affects pronominal and temporal interpretation. But DRT does not do justice to the complex interaction of pragmatic and semantic factors in discourse, and this leads to incorrect predictions about the way anaphora, both temporal and pronominal, is treated in DRT.

A clear example of where DRT goes wrong is with its analysis of temporal anaphora. DRT is right to make the contributions of tense depend upon the discourse context. But it attempts to make the temporal structure of a text almost completely dependent on the tense forms used in the text. In most natural languages, however, the temporal structure of the events introduced in a text is underdetermined by the sequence of tense forms. In particular, the rule above, which is a consequence of the DRS construction procedure, is false for French - a point of which some of the earliest workers on tense in DRT were aware - or English. Consider the following examples (from Lascarides and Asher 1993):

(5a) John entered the room. Fred greeted him.
(5b) John fell. Fred pushed him.

These two discourses employ the same sequence of tense forms, yet they suggest different temporal structures. DR-theorists have been forced to revise the construction procedure and to abandon the view that the tense forms and the order of the sentences in a discourse alone determine temporal structure. This conclusion follows not only from an examination of the English simple past but also from a careful look at the data concerning the French *plus que parfait* (see Asher and Bras 1992) and the English pluperfect (Lascarides and Asher 1992).

One might ask, what in combination with tense sequences determines the temporal structure? One proposal is that a more developed view of discourse structure is needed. Originally suggested by the computer scientist and artificial intelligence (AI) researcher Jerry Hobbs (1985), this thesis has been worked out in the context of a formal discourse semantics by Lascarides and Asher (1993). This approach to tense is part of a more general view: discourse structure has systematic effects on discourse interpretation, which it is the task of discourse semantics to study. As we shall see, both temporal and pronominal anaphora require a more elaborate discourse semantics.

3 More elaborate discourse semantics

When interpreters read a text, they naturally understand it as divided into parts related in various ways. Some parts form a narrative, others furnish a background to a narrative or an explanation of some action, still others may elaborate other parts of the text. Sometimes these divisions and the relations between them are signalled by punctuation and the presence of certain words in the text. But often interpreters infer the appropriate divisions and discourse relations without these cues. This sort of structure is completely missing from the treatment of discourse in DRT, but it has been recognized as an important aspect of discourse in other disciplines - for example, literary theory and the natural language processing (NLP) area of AI (see Artificial intelligence). In the mid-1970s, computer scientists like Roger Shank claimed text-understanding systems and text-information retrieval systems to be one of the central goals of NLP research in AI. This early interest led to a substantial amount of research on discourse structure in the mid to late 1980s (Polanyi 1988; Hobbs 1985; Grosz and Sidner 1985). This work has concentrated on the discourse structure of written texts, though analyses of highly structured, task-oriented dialogues have yielded important insights. Many divergent positions have been taken, but several uncontroversial conclusions have been drawn from these studies: (1) discourse is structured and can be represented by a set of

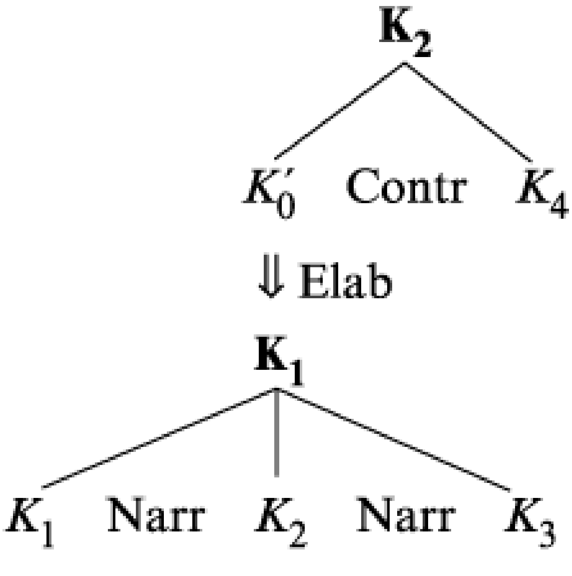
objects (propositions or bits of text) related by discourse relations; (2) this structure is hierarchical and recursive. For discourse semantics, we must integrate the view of discourse structure elaborated by these authors with a theory of meaning. This connection between semantics and discourse structure, however, is lacking in most of the discourse theories in AI.

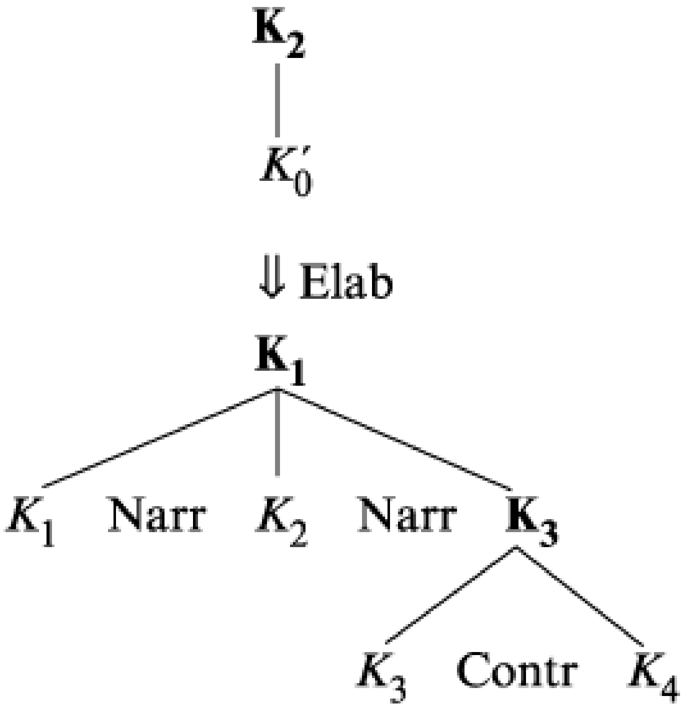
A richer notion of discourse structure is incorporated into the framework of dynamic semantics in Asher (1993), resulting in a nontrivial extension of DRT known as ‘segmented Discourse Representation Theory’ or SDRT. SDRT is one way to integrate discourse structure for texts and semantics. Another approach can be found in the works of Scha and his colleagues, but it exploits a different version of dynamic semantics.

According to SDRT, every discourse is analysed into a representational structure called a ‘segmented DRS’ or SDRS, and this is in turn embedded into a complete model that furnishes truth-conditions for the discourse. The model theory for SDRSs is somewhat involved, because the models must allow for quantification over and reference to dynamic propositions (for details see Asher 1993 or Asher 1996). An SDRS, like a DRS, is a pair of sets; but unlike a DRS the elements of the first set are either DRSs or SDRSs, while the second pair consists of a set of conditions in which discourse relations are predicated of elements in the first set. In comparing an SDRS for a narrative text with a DRS for the same text, we would see that the DRS is segmented into elements of the first set in the SDRS with discourse relations holding between these elements. These elements or ‘constituents’ of an SDRS serve several useful functions. First of all, they constitute referents for anaphoric pronouns (like ‘this’ in the example below) whose antecedents are facts or propositions:

(6) One plaintiff was passed over for promotion. Another didn’t get a pay increase for five years. A third received a lower wage than men doing the same work. But the jury didn’t believe this (any of this).

In the example above, we appear to have two possible antecedents (depending to some degree on how this is stressed): the proposition formed by the discourse as a whole and the proposition given by the last sentence. In SDRT these two anaphoric possibilities and only these two anaphoric possibilities are predicted; they result from two different, acceptable places to which the new information contained in the last sentence can be attached to the SDRS built up from the previous three sentences. Below we have a pictorial representation of the two SDRSs that could be constructed for (6). $K_1,\ldots, K_4$ represent the DRSs derived from the four sentences of the discourse; K_0' is a topic that results from the SDRS construction and the constraints on Narration (every Narration must have a nontrivial topic); the shadowed letters represent complex constituents or constituents that are SDRSs. The lines represent membership, while $\Downarrow$ represents a particular type of discourse relation (like Elaboration) that introduces a hierarchical structure into an SDRS. Narr stands for Narration, Elab for Elaboration, and Contr for Contrast. Notice the two different positions of attachment for K_4.





The crucial task for a discourse semantics like SDRT is to specify a procedure that will enable us to construct a discourse representation. In DRT the discourse representation is built up from the syntactic structure and a translation procedure for syntactic elements in the parse tree. SDRT exploits the DRS construction procedure to build DRSs for clauses, and it also makes use of the constraints DRT places on anaphora resolution. But in SDRT we need more information to be able to deduce where to attach new information in the antecedently built-up representation and by means of which discourse relation to attach it. The constraints on appropriate attachment sites are defined configurationally, following much of the work on discourse structure in AI. But the difficult part is to infer the appropriate discourse relation. Sometimes certain cue words or phrases indicate the presence of particular discourse relations, but those discourse relations may be present even when there are no cues. For instance, consider the following pairs:

(7a) John went to jail. He embezzled funds from the pension account.
(7b) John went to jail, because he embezzled funds from the pension account.

(8a) Mary went to school. She met with her students. She went home.
(8b) Mary went to school. Then she met with her students. Afterwards she went home.

Discourses (7a) and (7b) on the one hand and (8a) and (8b) on the other, lend themselves to the same interpretation. In the examples in (7), the second clause or sentence gives us the explanation for what happened in the first; while in (8), we read the clauses in each as narrating a sequence of events that are in the order that they are introduced in the text. Yet only in (7b) and (8b) are these interpretations fully determined by the semantic contributions of special ‘clue’ words like ‘because’ or the temporal adverbials in (8b). In (7a) and (8a), we infer the presence of an Explanation relation or a Narration relation based on pragmatic principles and the contents of the constituents the discourse relations tie together in the SDRSs for these discourses. However, this inference is not deductively valid; within a richer discourse context, we can cancel, for instance, the inference that the second sentence in (7a) offers an explanation of what happened in the first:

(7c) John went to jail. He embezzled funds from the pension account. But that is not why he went to jail.

But it also seems that the explanation relation is undeniably there in (7a). Thus, we must have a means of inferring discourse relations by default; the default or ‘non-monotonic’ inference of a discourse relation *R* can be overridden in cases where we have information in the context that is inconsistent with our conclusion that *R* holds. SDRT uses facts about the discourse context, the contents of the constituents including the lexical contents of particular words, world knowledge and pragmatic principles, to infer discourse relations non-monotonically. An attempt to code all

of this knowledge explicitly for certain simple examples is given in Lascarides and Asher (1993).

Once we have inferred that some discourse relation *R* relates new information to some available attachment point in the SDRS constructed from the preceding discourse, we can update this SDRS with the new information. But this updating does not consist in simple addition. It also requires in many cases the revision of the contents of the constituents in the SDRS. It is in the process of constituent revision that anaphora resolution and the determination of temporal structure are accomplished in SDRT. For instance, consider again the discourse in (4). The *passé simple* of the verbs in this text all introduce the simple DRS condition saying that the eventuality described by the verb occurred prior to the speech point. There is no attempt in the semantics to link up the eventuality with the temporal structure built up antecedently, as there is in DRT. But now the underlying logical inference mechanisms of SDRT discussed above lead us to conclude that Narration relates the constituents α and β derived from the first two sentences and the constituents β and χ derived from the second and third sentence. According to SDRT, Narration has certain temporal effects: $\mathrm{Narration}(\alpha, \beta) \rightarrow \mathrm{e}_\alpha < \mathrm{e}_\beta$. So once we have attached the three constituents in (4) with Narration, we immediately conclude that the text gives us a sequence of events that follows the order in which these events are introduced in the text. The effect of Narration is one way to formulate precisely part of Grice's maxim 'be orderly'. The order of presentation of the events in the text reflects their temporal order (see Implicature §4). But the pragmatic principles appealed to in the formalization of Lascarides and Asher (1993) and used to infer that Narration holds between these constituents are a good deal more specific than the general Gricean maxims of conversation, and they are expressed in logic.

In (5b) additional information contained in the two clauses leads us to defeat the inference to Narration and to conclude that a different discourse relation - Explanation - holds between the two constituents of the SDRS. Explanation has different temporal consequences from Narration: $\mathrm{Explanation}(\alpha, \beta) \rightarrow \neg(\mathrm{e}_\alpha < \mathrm{e}_\beta)$ and, where '$>$' is a weak conditional used to represent default patterns, $\mathrm{Explanation}(\alpha, \beta) > (\mathrm{e}_\beta < \mathrm{e}_\alpha)$. So we conclude that in (5b) the pushing came *before* the falling, as intuitions would dictate. Thus, while DRT attempted to derive the temporal structure of a text from the semantics of the sequence of tenses in a discourse alone, SDRT exploits not only the compositional semantics but also many other sources of information that contribute to discourse structure to determine temporal structure.

4 Conclusions

Because of the rapidity with which the field of discourse semantics has evolved, it is hard to say exactly where the field will develop or even whether it will continue as a field. It is quite unclear whether DRT or SDRT will remain active research areas. SDRT has been applied not only to the central discourse semantic concerns of temporal and pronominal anaphora, but it has also helped in analysing the spatiotemporal structure of texts (Asher *et al.* 1994), the role of discourse structure in lexical disambiguation (Asher and Lascarides 1995), and the interactions between discourse structure and speakers' and interpreters' cognitive states - in particular their beliefs and discourse goals (Asher and Lascarides 1994). To advance further, SDRT and other formalisms for discourse semantics require a better understanding of the organization of the lexicon and of the role of general world knowledge. As discourse semantics moves to give a formally precise analysis (capitalizing on empirical studies) of discourse interpretation in dialogue, other factors like the interaction between semantics and speech acts will have to be taken into account (see Speech acts).

Discovery, logic of

Bacon, Descartes, Newton and other makers of the Scientific Revolution claimed to have found and even used powerful logics or methods of discovery, step-by-step procedures for systematically generating new truths in mathematics and the natural sciences. Method of discovery was also the prime method of justification: generation by correct method was something akin to logical derivation and thus the strongest justification a claim could have. The 'logic' of these methods was deductive, inductive or both. By the mid-nineteenth century, logic of discovery was yielding to the more flexible and theory-tolerant method of hypothesis as the 'official' method of science. In the twentieth century, Karl Popper and most logical positivists completed the methodological reversal from generativism to consequentialism by setting their hypothetico-deductive method against logic of discovery. What is epistemologically important, they said, is not how new claims are generated but how they fare in empirical tests of their predictive consequences. They demoted discovery to the status of historical anecdote and psychological process. Since the late 1950s, however, there has been a revival of interest in methodology of discovery on two fronts - logical and historical. An earlier explosion of work in symbolic logic had led to automata theory, computers, and then artificial intelligence. Meanwhile, a maturing history of science was furnishing information on science as a process, on how historical actors and communities actually discovered or constructed their claims and practices. Now, in the 1980s and 1990s, liberal epistemologists once again admit discovery as a legitimate topic for philosophy of science. Yet attempts to both naturalize and to socialize inquiry pose new challenges to the possibility of logics of discovery. Its strong associations with 'the' method of science makes logic of discovery a target of postmodernist attack, but a more flexible construal is defensible.

1 Logic and method

A logic of discovery in the narrowest sense would be a valid reasoning procedure that leads to new knowledge. More broadly, 'logic of discovery' includes routine methods and research techniques that contain inductive or heuristic steps and sometimes produce new knowledge claims that need further justification. A heuristic procedure is a shortcut that compromises the reliability of an algorithm for greater speed or efficiency. In the broadest sense of discovery as an achievement, 'logic of discovery' or the discovery process includes the entire research effort from the first tentative posing of a problem to the 'final' testing and accepting of a solution as adequate.

Does deductive logic constitute a logic of discovery in the narrow sense? The usual objection - that deductive argument is not ampliative - confuses logical with epistemic novelty and 'amplification'. True, the conclusion contains no more logical content than the premises collectively, but it may contain more epistemic content, relative to the current state of knowledge. Strictly deductive arguments in mathematics, logic and the sciences have led to astounding (epistemically novel) conclusions. Since deductive arguments may have empirical premises, and hence empirical conclusions, this reply also blunts the related objection that deductive methodology is a priori and so cannot generate new empirical claims. Deductive reasoning from what we already 'know' can yield empirical conclusions that are epistemically novel, even revolutionary; for example, the Lorentz transformation is derivable from a mathematically generalized form of the Galilean transformation plus the 'empirical fact' that the speed of light is constant (see Relativity theory, philosophical significance of §1).

A more serious objection to deductive logic of discovery is that it is not a method or procedure and hence provides no guidance to discovery. It is a logic of justification that tells us whether a proof is valid, but it does not show us how to find such proofs.

Relaxing deductive strictures to allow inductive methods does yield low-level logics of discovery. An example is Reichenbach's inductive method, based on repeated self-correcting applications of his 'straight rule' (see Reichenbach, H. §3). Factor analysis and other probabilistic and statistical methods furnish inductive discovery procedures, but we cannot expect these methods alone to produce novel, deep-structural theories.

Another way in which to 'relax' deductive logic into a useful method is to add heuristic rules, for example, rules that instruct us to search first for an answer here or to try A, B and C, in that order. Heuristic rules in the form of 'production rules' (if the situation is X, then do Y) are central to the work of Allen Newell, Herbert Simon and others in artificial intelligence (AI) (see Artificial intelligence §2). Their motivating idea is that discovery is problem-solving behaviour; hence, what we already know about problem solving can be transferred to

methodology of discovery. And we know that problem solving typically involves heuristic search through spaces or ’trees’ of possible solutions. They claim that their BACON and KEKADA programs have rediscovered laws of Kepler, Black, Ohm, Krebs and others (see Langley *et al.* 1987).

While Simon’s group prefers to employ very general heuristics, others employ heuristics that are highly content- and context-specific. In effect they answer the above a priori objection by employing heuristics laden with theoretical and empirical content specific to the discipline or even the particular problem at hand. In AI this corresponds to the move from general problem solvers to knowledge-based or ’expert’ and case-based systems. This move is motivated by the quest for greater problem-solving power. Roughly speaking, the more powerful the program, the more specific its sphere of application.

Developments in AI represent the ’logical’ wing of methodology of discovery. The ‘historical’ wing was inspired by a post-war ’internalist’ history of science, which showed that typical discoveries are discursive, structured in time. Accordingly, historical philosophers reject as overly romantic the view that discoveries are momentary, irrational inspirations. But finding no uniform logic of discovery, some defend the epistemic interest of discovery by retreating from logic to claiming the rationality of discovery and by contending that mode of discovery can be relevant to justification and hence to epistemology. Some writers interpose a third stage - prior appraisal, preliminary evaluation or heuristic appraisal - between original generation of ideas and ’final’ justification. Few historicists fully embrace AI accounts of discovery. Historicists doubt whether we do know enough about problem solving in general to capture the richness of historical investigations in the form of AI programs.

AI advocates retort that the historical approach is too vague to explain much. An adequate explanation of historical discoveries must be ’computational’: it must furnish a program capable of actually re-making the discovery in question, given the historically relevant problems and data. On strong versions of this view, an adequate discovery explanation posits something akin to a constructive proof already available to the historical actors and used by them to make that discovery! Historicists reply that this demand puts the cart before the horse and imputes foreknowledge to the actors; that, typically, routinized problem-solving procedures are later, refined products or parts of the total discovery rather than antecedently available explainers of it. Historicists complain that the AI programs employ cleaned-up text-book versions of Kepler’s and others’ problems and data and thus illegitimately reverse the order of knowing by imposing present conceptions on the past. They whiggishly sacrifice historical reality to AI production values.

2 Is there a logic of discovery?

The question is ambiguous and has been understood in at least three ways.

(1) Does there exist, in the abstract mathematical sense, one or more logics (routine methods) of discovery?
(2) Do/did scientists actually possess one or more logics of discovery?
(3) If so, does their knowledge of methods of discovery explain any historical discoveries?

To those who engage in highly formal studies of type (1), for example machine learning theory, historical issues are simply irrelevant. For them the question of existence is mathematical-ontological, not historical. However, a formal existence proof does not in itself produce a method actually usable on the frontier of research. Accordingly, most methodologists have been more interested in (2) and (3). (2) puts the question in epistemological rather than ontological terms, while (3) concerns historical and historiographic application.

Is there a logic or method of discovery in senses (2) or (3), a systematic and routine way of attaining new knowledge? Can the Scientific Revolution be partially explained in terms of new methods of discovery? Most methodologists agree that there is no single method of discovery, let alone a single ‘method of science’, understood as something that gives precise direction to inquiry. However, in a weaker and more local sense, we surely do possess numerous routinized problem-solving methods, procedures that would immensely impress a Descartes or a Newton. While these procedures do not, all by themselves, generate deep new theories, they do help us organize in fruitful ways both extant knowledge and our knowledge-productive powers; and the semi-automated (computer-aided) modelling techniques available in many sciences can guide the construction of serious, deep theory candidates (see Models).

Actually, the epistemic importance of discovery, here understood as initial generation of a claim, would seem to be

secure, whether or not there is a method or even a rationality of discovery in some pre-specified sense. For if we are ever to find true, correct or adequate claims and techniques, they must first be generated in some way, whether by a rational, methodical process or not. A correct claim has no chance of being selected (justified) unless a discovery process first puts it on the table for further consideration. Thus, manner of generation is relevant to epistemology. But this point must not be overrated, for the epistemic importance of discovery in this broad sense does not entail the existence of a method or logic, or even the rationality, of discovery.

The principal objection to there being rules for discovery is that ’creative routine’ is a contradiction-in-terms. Romantic poets long ago raised this objection: originality, by definition, cannot be a product of rules. (They do have a point, but do they not also confuse epistemic and logical novelty?) More recently, from a different quarter, evolutionary epistemologists such as Karl Popper (1959) and Donald Campbell (1960) have contended that ’logic of discovery’ is an oxymoron. They in effect raise the a priori objection of §1 from the opposite side: a genuine logic of discovery is impossible, for it would require prescience or clairvoyance - knowing now what we shall only find out later. On the frontier of knowledge, says Campbell, we can only proceed blindly. At the absolute frontier of research, there can be no method to guide us. All genuine creativity in the arts and sciences amounts to blind variation plus selective retention $(\mathrm{BV}+\mathrm{SR})$, which is basically the mechanism of biological evolution. This claim threatens both AI and historical methodologies of discovery.

Methodologists of discovery respond that actual research, even on the frontier, looks more directed than this; hence, there remains some scope for method, with its concern for economy of research. From the perspective of methodology as a sort of managerial science of our limited epistemic resources, $\mathrm{BV}+\mathrm{SR}$ is the most wasteful form of production there is. It introduces no ’quality control at the source’ but instead tests and discards almost everything at the justificatory ’selection’ stage. Reducing discovery to blind luck is precisely what Bacon and Descartes wished to avoid. And, in fact, historical investigators have nearly always been guided by powerful constraints at the generation stage. Evolutionary epistemologists reply that guiding heuristics are often available but that we must consider them, in turn, as ultimately products of previous hierarchies of $\mathrm{BV}+\mathrm{SR}$. Thus it would be wrong to see Campbell and Simon as being totally opposed.

3 Some problems and prospects

Many critics dismiss logic of discovery as a historically dated subject; yet, understood as a broad topic area rather than a specific method, it engages several intellectual developments. We can conceive logic of discovery as the study of knowledge amplification in all its forms; whence it embraces all the ways in which scientific claims are constructed. We need not cast the issues in terms of false dilemmas such as history versus logic, social constructivism versus realism and logic versus rhetoric. On the contrary, discovery logics (routinized modes of problem solving, model construction, and data analysis) are themselves discovered or constructed and maintained as succeeding generations reconstruct and refine the work of their predecessors. And the rhetoric of inquiry (including problem representation, modelling, learning by example, and point-of-view in problem solving) is crucial to creative cognition. Rhetoric helps both to familiarize the unfamiliar and to de-familiarize the familiar. Kuhn (1962) and current AI and cognitive psychological work on learning by example, by exemplars rather than rules, suggests that the rhetoric of inquiry is, in part, a sort of fuzzy logic of discovery. Kuhnian exemplars constitute a system of rhetorical places or concrete models for ongoing work at the frontier. It is noteworthy that nearly every philosophical account of learning, theory structure, theory reduction, modelling, and so on, ultimately depends on analogy, metaphor, similarity relations, and other rhetorical tropes.

Heuristic appraisal, the evaluation of the promise or fertility of a problem, theory, technique or research proposal is a ’discovery’ topic that deserves more study. It is immensely important, as scientists and funding committees must base nearly all of their decisions on heuristic appraisal. But how is it possible to go beyond an item’s ‘track record’ to evaluate its future promise? Here discovery intersects the central epistemological problems of futurology: what can we know about possible futures, and how?

A related issue, the more important insofar as successful logics of discovery are local and content-specific, is to what extent these methods can be applied in other areas. This is one form of the problem of transfer of technology and connects with problems of standardization. There may be no scientific method that is at once universal and deeply instructive, but scientists nonetheless want to generalize the more modest results that they do have, to make as much of the world as possible scientifically intelligible. Far from presupposing the existence of a fixed scientific

method, logics of discovery are themselves products of discovery/construction. Even the logical and rhetorical discovery and constitution of new sciences falls under discovery, broadly understood.

Discrimination

A principle forbidding discrimination is widely used to criticize and prohibit actions and policies that disadvantage racial, ethnic and religious groups, women and homosexuals. Discriminatory actions often rely on unfavourable group stereotypes and the belief that members of certain groups are not worthy of equal treatment. A prohibition of discrimination applies to the distribution of important benefits such as education and jobs, and says that people are not to be awarded or denied such benefits on grounds of characteristics such as race, ethnicity, religion or gender. Attempts have been made to expand this principle to cover institutional *discrimination. Discrimination is morally wrong because its premise that one group is less worthy than another is insulting to its victims, because it harms its victims by reducing their self-esteem and opportunities, and because it is unfair.*

1 The anti-discrimination principle

Prejudice and ethnic hostility, and the discrimination and other forms of intolerance that they generate, are found in all parts of the world. Prejudice typically involves a negative attitude towards a group based on a belief that members of the group are undeserving of equal treatment because they are somehow inferior or morally deficient. Prejudice often relies on stereotypes - simplified and negatively slanted conceptions of the typical characteristics and activities of members of the group. Racism is one species of prejudice; other species include bigotry, sexism, extreme nationalism and homophobia.

The moral norm that makes discrimination wrong can be formulated as follows:

The anti-discrimination principle. When distributing educational opportunities and jobs [*list of items*], never exclude whole groups of persons or choose one person over another on grounds of race, ethnicity, religion, or race [*list of excluded characteristics*] unless the use of these characteristics in particular circumstances is demonstrably legitimate and important.

This anti-discrimination norm is presupposed by most condemnations of discrimination, and is found in most civil rights legislation (Brest 1976). It rejects ways of thinking that assume the inferiority or depravity of certain groups, and forbids some of the most important ways of acting and deliberating that flow from such assumptions. Because it is concerned with the grounds on which decisions are made (and thus with people's reasons and intentions), proving that discrimination has occurred is often difficult.

The anti-discrimination principle forbids those distributing certain benefits and burdens to 'choose … on the basis of …' certain excluded characteristics. This regulates the process of selection, but only indirectly regulates its outcomes. It does not forbid an employer to deny employment to a Muslim, if that is the outcome of a non-discriminatory selection process, but it blocks the employer from using an applicant's Muslim beliefs as a reason in deciding whether or not to employ the applicant. Formal or informal statements of qualifications cannot mention religion or other excluded characteristics. The anti-discrimination principle says how *not* to allocate certain important benefits, but it does not say how they should be allocated. It does not, for example, prescribe that these benefits should be allocated in accordance with competency or qualifications. Goldman (1979) has defended the additional principle that employment and selection for advanced education should always be on the basis of competence.

The formulation of the anti-discrimination principle given above is too narrow. The two bracketed clauses (the 'list of items' and the 'list of excluded characteristics') mark slots that need to be filled in more adequately. The list of items could be expanded by listing, along with educational opportunities and jobs, matters such as housing, public accommodation, legal rights, opportunities for political participation, public assistance and military service. Perhaps the underlying idea here is to focus on benefits and burdens that have a major impact on people's prospects, long-term welfare and self-respect, and whose distribution can be regulated without deeply invading people's liberties. The anti-discrimination principle does not apply to the distribution of all benefits and burdens. It does not forbid, for example, choosing someone who shares one's religion as a friend, or using gender as a factor in choosing a spouse.

The list of excluded characteristics could be expanded beyond race, ethnicity, religion and gender to include national origin, political beliefs, being a non-citizen, sexual orientation, income and age. It is sometimes suggested

that an anti-discrimination principle should exclude reliance on characteristics that are ‘irrelevant’ or ‘arbitrary’. What makes this plausible is the fact that one’s religious beliefs, for example, have little bearing on one’s qualifications to work in a construction company. Choosing people for construction work on the basis of their religion just seems irrational. But if the owners of a large construction company seek to employ only fellow Christians because they think they are more likely to be honest and hard-working, or because they want to create a certain religious atmosphere within the company, they cannot be faulted for making arbitrary choices or using irrelevant criteria. The problem is rather that these selection procedures are inappropriate for a large company in a diverse country because they are unfair to non-Christians.

2 Institutional discrimination

The anti-discrimination principle is narrow in its scope and the occurrence of discrimination is often hard to prove. Thus it is unlikely that widespread acceptance and legal enforcement of the principle will quickly stop discrimination or eliminate the consequences of past discrimination. Affirmative action programmes, which go beyond anti-discrimination, are intended to do these things more rapidly (see Affirmative action). But many have attempted to expand the scope of the anti-discrimination principle to cover *institutional* discrimination (Banton 1991; Ezorsky 1991). There are at least five sorts of phenomena that a norm addressing institutional discrimination might cover.

(1) *Unconscious discrimination*. To engage in discriminatory behaviour one does not have to be aware that one is doing so. One can discriminate by relying on stereotypes one is unaware of or by unconsciously following old customs. This sort of discrimination can be brought under the anti-discrimination principle by defining ‘choose … on grounds of …’ in a broad enough way to cover decisions that unconsciously rely on stereotypes and discriminatory customs.
(2) *Statistical discrimination*. Characteristics that are relevant to selection for a position often are statistically correlated to some degree with characteristics such as race, ethnicity and gender. An employer may refuse, for example, to employ a woman in a warehouse because they believe correctly that most women are unable to lift the heavy boxes stored in the warehouse. Although the likelihood that one can do a certain kind of job is generally an appropriate basis for selection, it is discriminatory to exclude all women from jobs requiring heavy lifting on the grounds that most women are unable to do it. Lifting abilities are easy to test on an individual basis, and hence it is fairer to require that people be selected as individuals rather than on the basis of some class to which they belong. Statistical discrimination can be excluded by the anti-discrimination principle if we specify that ‘choose … on the basis of …’ covers and thus forbids using the excluded characteristics as statistical indicators of the presence or absence of qualifications.
(3) *Reaction qualifications*. When the customers of a business are prejudiced it may be rational for the business to conform to those prejudices in choosing its employees. It is not in general wrong to select people for positions on the basis of the preferences of the people they will serve. If customers like travel agents with pleasant personalities there is nothing wrong with making the possession of such a personality a job qualification for travel agents. Thus we cannot say that it is arbitrary to select people on the basis of reaction qualifications, but in some contexts it is discriminatory to do so. Wertheimer (1983) argues that relying on reaction qualifications based on race and gender often leads to injustices. It may be possible to bring reaction qualifications under the anti-discrimination principle by extending ‘choose … on the grounds of …’ to cover choosing on the basis of one’s customers’ prejudices.
(4) *Personal connections*. Ezorsky (1991) argues that finding new employees by word-of-mouth advertising within the social networks of one’s present employees is discriminatory towards blacks in contexts where blacks have been excluded from employment by past discrimination and where residential segregation persists. Although this method of recruiting employees might be unobjectionable in some circumstances, it is discriminatory in societies with a history of racism. To prohibit this sort of discrimination we probably have to go beyond the negative anti-discrimination principle to a supplementary requirement that jobs be advertised publicly and that employment through personal connections be avoided.
(5) *Legacy of discrimination*. Allocative decisions can transmit a legacy of discrimination even though they themselves are not discriminatory in the standard sense. Black people growing up in the southern states of the USA in the 1950s were likely to have had educational opportunities inferior to those of whites and to have faced substantial discrimination in seeking employment when they left school. Thirty years later, when such a person sought a job from a company that had fully non-discriminatory hiring policies, they could well have had a less

good record of work experience than a white who was not disadvantaged early on by discrimination in education and employment. Choosing a white person because of better work experience in such a case would not be directly discriminatory, but it would transmit the legacy of discrimination. How to address this sort of case seems more a matter of affirmative action than anti-discrimination.

3 What makes discrimination wrong?

Consider a clear violation of the anti-discrimination principle, such as an employer prejudicially refusing to hire or even consider blacks for work in a restaurant. What is wrong with such an action? First, it is insulting to blacks because of its underlying premise that some racial groups are less worthy than others. Second, it is harmful to blacks because it often reduces self-esteem and produces a sense of inferiority, and because it deprives people of opportunities that would have allowed them to live better lives and make greater contributions to society. Discrimination in education and employment will tend to reduce a group's aspirations and productivity by reducing the payoff of investments in education and work experience. Third, discrimination is often irrational. It frequently relies on unjustified beliefs and stereotypes, and selects people on irrelevant and arbitrary grounds. Although it is not in general morally wrong to act irrationally, irrational actions that distribute important goods in ways that harm and disadvantage other people may indeed be wrong because they are unfair. Finally, the most important reason why discrimination is wrong is that it is unfair. Victims of racial discrimination in employment, for example, can legitimately complain that as full members of society who have done their part in preparing to participate in and contribute to society it is unfair for them to be handicapped in areas such as education, employment and politics by discrimination flowing from other people's prejudices.

Dissoi logoi

Dissoi logoi ('Twofold Arguments') is the title scholars apply to a short anonymous collection of arguments for and against various theses. The work, in Greek, is (questionably) dated around 400 BC, and regarded as an interesting, if second-rank, product of the Sophistic age.

The opening sentence of *Dissoi logoi* announces 'twofold arguments' about good and bad: one set to show that good and bad are the same, another to show they are different. Chapters 2-4 follow the same pattern for the opposites seemly and shameful, just and unjust, true and false, respectively. Chapters 5-7 argue for and against a thesis, respectively: 'The demented and the sane, the wise and the ignorant, both do and say the same things', 'Wisdom and virtue cannot be taught or learned' and 'Public offices should be assigned by lot'. Chapter 8 argues positively for the idea that a good speaker will know everything. Chapter 9 recommends the art of memorization, but the manuscripts break off leaving both chapter and treatise incomplete.

This is a mere summary of the document. Nothing can be said with certainty about it. Not only its author, but its text, date, overall purpose and intellectual affiliations remain matters for scholarly speculation. Speculation has run riot.

To begin with the text: its Doric dialect is marred by intrusions of Attic and some Ionic forms. Is this due to the tendency of scribes to normalize the texts they copy? To a non-Doric speaker writing for a Doric-speaking audience? Or did a Doric author rewrite an earlier text? Imperfect Doric betrays numerous forgeries ascribed to early Pythagoreans but produced long *after* 400 BC. The antique feel to the text could be misleading.

What of the standard dating? This rests largely on a mention of the Peloponnesian war (431-404 BC) as the most recent of a series of notable wars going back, via the Persian and Trojan wars, to the battle of the gods and giants. Was there a comparable war between 404 BC and Rome's conquest of the Hellenistic kingdoms? If not, the *Dissoi logoi* could have been written centuries after 404 BC.

Concerning the overall purpose of the piece, on the standard dating, the best guide is Aristotle's description (*Sophistical Refutations* 183b36-184a1) of earlier methods of teaching rhetoric and dialectic: the idea was that memorizing specimen arguments would somehow equip the student to produce, at the appropriate juncture, new instances of a typical pattern. On this hypothesis, the author's intellectual affiliations are not discernible from first-person remarks like 'I assert this latter view' (4.2). These belong to the argumentative strategies a student must memorize. That sometimes the author appears to endorse both sides of the dispute must be disregarded: 'I' does not refer to the author but to the speaker in some imaginary debate.

It is not a high-powered debate. Many of the arguments for and against do not even manage to contradict each other. Good and bad are the same because the same thing is good in some circumstances, bad in others; they are different because 'good' and 'bad' mean different things. 'I am an initiate' is both false (in your mouth) and true (in mine); yet 'false' and 'true' mean different things.

Scholars seek influences and sources for particular arguments in the collection: Protagoras and Hippias are especially popular. But most of what we 'know' about individual Sophists is itself speculation (see Hippias; Protagoras; Sophists). Besides, time moves slower in philosophy than in life: arguments and examples get repeated for centuries after their first appearance. The arguments in chapter 6 for and against the teachability of wisdom and virtue show numerous points of contact with Plato's *Protagoras* (319a-328d) and *Meno* (89e-96d). Is Plato drawing on themes already broached in the *Dissoi logoi* or did our author draw on Plato? Neither conclusion is safe. Philosophy being what it is, statements like 'before now people have frequented sophists and gained no benefit' (6.5) could easily be written when the 'Sophists' were a phenomenon of the distant past.

So why were these feeble arguments preserved? The *Dissoi logoi* survives in fact as an appendix to the manuscripts of Sextus Empiricus, who regularly argues for and against a thesis to induce suspension of judgment about it. This suggests the collection was of interest to Pyrrhonian sceptics, either for historical reasons or because, according to these sceptics, even feeble arguments are useful as the appropriate cure for milder cases of dogmatism (Sextus Empiricus, *Outlines of Pyrrhonism* III 280-1). A sceptic called Zeuxis, a friend of aenesidemus, wrote *On*

Dissoi Logoi (Diogenes Laertius, IX 106). Both Pyrrho himself and his follower Aenesidemus came from Doric-speaking regions. Could Zeuxis be commenting on the *Dissoi logoi*, supposing or pretending it was antique?

Like all suggestions about the *Dissoi logoi*, the above is speculation. Sober readers will suspend judgment on every question about the work.

Dodgson, Charles Lutwidge (Lewis Carroll) (1832-98)

Dodgson, an Oxford teacher of mathematics, is best known under his pseudonym, Lewis Carroll. Although not an exceptional mathematician, his standing has risen somewhat in the light of recent research. He is also of note as a symbolic logician in the tradition of Boole and De Morgan, as a pioneer in the theory of voting, and as a gifted amateur photographer. His literary output, ranging from satirical pamphleteering, light verse and puzzle-making to an immense correspondence, is again largely amateur in nature, and would hardly have survived without the worldwide success of his three master-works, Alice's Adventures in Wonderland (1865), Through the Looking-Glass (1871) and The Hunting of the Snark (1876). Together with portions of his two-volume fairy-novel Sylvie and Bruno (1889/93) they are the only writings, ostensibly for children, to have attracted or deserved the notice of philosophers.

Dodgson was the eldest son of a North-of-England clergyman. From Rugby School he went on to Christ Church, Oxford, where he obtained a first in mathematics and, in due course, a lectureship which he held for the rest of his working life. A prim, sentimental bachelor clergyman, Dodgson himself was no philosopher; his diaries and letters record the banalities of his London theatre-going, child friendships and contacts with the art world, but reflect throughout a busily inventive rather than a deeply thoughtful mind. Mainly through photography, he got to know a number of eminent people, from Tennyson, Ruskin and the Rossettis to Lord Salisbury, the Prime Minister, but never himself figured as a literary lion, still less a Victorian sage. As Dodgson the mathematician, he would even disclaim authorship of the *Alice* books, never suspecting that these would be the works to bring him philosophical fame, not merely as a fount of allusion for logical analysts but also as an ample wabe for the gyrings and gimblings of literary theorists across the English Channel.

To the analytical philosopher, *Wonderland* provides a wealth of bad arguments on such themes as the criteria of reality and personal identity, the relativity of space and size, the effects of arrested time and causality-reversal, the theory of types, the status of nonentities and the paradoxes of solipsism and idealism. Although nobody imagines that the Mad Hatter, Tweedledee or the White Queen have any serious light to shed on these matters, their dicta remain perennially useful as a model of how not to think, and are freely cited by the likes of Russell, Moore, Broad and even Wittgenstein.

By French neo-structuralists, on the other hand (notably Deleuze and Lecercle), the Carrollian corpus is elevated to a far more solemn significance, and taken to afford genuine insight into the logic of dreams and madness, the nature of nihilism and nonsense, the collapse of all differences between names and things, the deconstruction of language by puns and portmanteau-words, and its ultimate subjugation under the stipulative dictatorship of a Humpty-Dumptyan subject. Like the Freudian commentators of an earlier generation, who found cannibalism and psychosis everywhere they looked in *Alice*, the postmodern critics have discovered in it themes and purposes that would have horrified the author, supposing that anyone could have explained them to him.

That *Alice* has influenced a host of modernist writers, from Kafka and Joyce to Borges, Ionesco, Nabokov, Beckett, Artaud and the entire surrealist movement, it would be idle to dispute. But before Mr Dodgson, the pedantic Oxford logician, is thereupon canonized as an apostle of anarchy and irrationalism, it needs to be stated in his defence that the Carrollian absurd, whatever its consequences, is so far from being morbidly antirational in origin that it issues directly from the nature of logic. Formal logicians care nothing for the content of their propositions; they only want to know the consequences. As arbitrary class-names, snarks and boojums, cabbages and kings, bats and tea-trays, beavers and butchers and things that begin with an 'M' are all equally serviceable as terms for the syllogisms that Dodgson delighted in, and what is the harm, then, in animating them with a touch of fictional life? Carroll, so regarded, is in no way a deconstructor of the established order. He is simply one more in the long line of logical humorists, stretching from Zeno, Euthydemus and Buridan to his own mentor, De Morgan, and continuing thereafter via F.C.S. Schiller to Russell, Jourdain, Quine and Raymond Smullyan. It should be no surprise to anyone, therefore, that all five of the last-mentioned are known devotees of *Alice*.

PETER HEATH

List of works

For details of the following works, the reader is advised to consult *The Lewis Carroll Handbook*, ed. S. Williams *et al.*, listed in References and further reading.

Carroll, Lewis (1865) *Alice's Adventures in Wonderland*, London: Macmillan, 1866.
Carroll, Lewis (1871) *Through the Looking-Glass*, London: Macmillan.
Carroll, Lewis (1876) *The Hunting of the Snark*, London: Macmillan.
Dodgson, C.L. (1879) *Euclid and his Modern Rivals*, London: Macmillan.
Carroll, Lewis (1885) *A Tangled Tale*, London: Macmillan.
Carroll, Lewis (1886) *The Game of Logic*, London: Macmillan.
Carroll, Lewis (1889) *Sylvie and Bruno*, London: Macmillan.
(1893) *Sylvie and Bruno Concluded* , London: Macmillan.
Carroll, Lewis (1896) *Symbolic Logic*, Part I, London: Macmillan.

Rambling and undependable, it remains, for all that, the chief source of bibliographical information and a necessity for the serious student or collector.)

Dōgen (1200-53)

Dōgen Kigen, the founder of Japanese SōtōZen Buddhism, is most noted for his argument that meditation is the expression or enactment of enlightenment, not the means to attaining it. Dōgen believed that even a novice might achieve insight, however fleeting. The difficulty, however, is in expressing that insight in one's daily acts, both linguistic and non-linguistic. In developing his position, Dōgen articulated a phenomenology of incarnate consciousness and a sophisticated analysis of meaning. His theories of mind-body unity, contextualized meaning, temporality and theory-praxis influenced many prominent modern Japanese philosophers such as Watsuji Tetsurō, Tanabe Hajime and Nishitani Keiji.

Tradition states that Dōgen was of aristocratic background and orphaned at the age of seven. A few years later he entered the Tendai Buddhist monastery on Mount Hiei, one of Japan's great spiritual and intellectual centres of the time. He left the monastery at seventeen because he could not resolve an apparent contradiction in Tendai doctrine, the idea that spiritual practice to achieve enlightenment is necessary even though we are all already somehow inherently enlightened. His quest took him to China in 1223 where he studied under the Chinese Chan (Zen) master Rujing (1163-1228). Dōgen returned to Japan in 1227 with Rujing's verification that he had achieved enlightenment and was a Zen master in his own right. In Japan, Dōgen wrote a series of innovative essays, many on philosophical subjects, later collected as *Shōbōgenzō(Treasury of the True Dharma Eye)*. He spent the final decade of his life establishing a comprehensive monastic community in the isolated mountain regions of today's Fukui prefecture. Sōtōeventually became the most popular form of Zen Buddhism in Japan with a strong following among the laity.

Dōgen was a philosophical realist insofar as he maintained we have access to 'presencing of things as they are' (*genjōkōan*). However, that presence is inherently meaningless. Meaning only arises within context, and context always involves an act of human consciousness. Hence, a simple correspondence between what-is and what-is-thought is not possible (see Truth, correspondence theory of). The nature and function of context must also enter into the consideration of truth and falseness.

Dōgen sometimes drew on the traditional Buddhist example of the ocean. To a fish the ocean is a translucent palace; to a person at sea, it is a great circle extending to the horizon in all directions; to a heavenly being, it is a shimmering string of jewel-like reflections. What is the ocean in itself? Dōgen maintained it is intrinsically none of those things, yet has the capacity to be all of them. The meaningless presence is expressed by such vacuous Buddhist terms as 'suchness', 'thusness' or 'emptiness'. Yet, in the fish's context, the sea truly becomes a palace; in the person's it is a circle, and in the heavenly being's it is jewel-like reflections. In itself, the presence (the ocean) is simply the not-yet-conceptualized, meaningless reality that can be contextualized and made meaningful in an infinite number of ways.

For Dōgen, therefore, error is possible by either overly absolutizing or overly relativizing meaning. Fixed in only one context of understanding, one may absolutize its meanings, assuming them to exist independently of consciousness as the things themselves. For example, although the fish would be correct to think in its context that the presence is a palace, it would be wrong to think that it can *only* be a palace. Alternatively, one may err in the direction of extreme relativism. Because there are a limitless number of contexts giving meaning to the presence as, for example, 'palace', 'circle' or 'jewels', this does not imply the presence can assume any meaning whatsoever. Such extreme relativism would be wrong on two counts. First, in each specific context there is only one correct meaning; to the person at sea, for example, the presence is not a palace. Second, there can be some attributed meanings that cannot be correct in any context. Dōgen gave the example of time as 'flying away'. Since the idea itself is logically incoherent (at what rate does time fly?), it can never be true in any context.

For Dōgen these ruminations on presence, context and meaning had implications for Zen practice. He believed the anxiety of everyday life arises from misunderstanding meaning and misreading contexts. We become fixed in interpreting the world as if there were only a very limited number of possibilities. We force our interpretations to fit that limited repertoire of contexts. This inhibits our capacity to adjust to change, and in fact encourages us to deny the reality or importance of both change and context. Zen practice addresses this predicament in two ways.

First, Dōgen believed that Zen meditation, 'just sitting', is a method for disengaging the normal meaning-bestowing function of consciousness. In the non-affirming, non-negating mode he called 'without thinking', one can encounter phenomena in their contextless, meaningless state. In this respect, insight into presence is immediately available to anyone. Yet, human life requires meaning; thus the second function of Zen meditation is to be aware of the contextualizing, meaning-bestowing process, watching it structure the formerly inchoate 'presence'.

It is extremely difficult to distinguish whether one is watching a spontaneous unfolding of contextual meaning or a projection of a previous meaning on to the phenomena. Therefore, the student benefits from a master who continually shifts the context of discourse and action, requiring the student to express new meanings appropriate to the shifts. To the extent the master does the unexpected, the student becomes aware of having had an expectation, a contextual presupposition about what is meaningful in the situation. The master's actions deconstruct those expectations, those fixed meanings. In Dōgen's terminology, the 'master and student practise together' by opening each other to new vistas of expressive meaning, each true to the newly emergent context. This type of practice, Dōgen maintained, is the expression or enactment of enlightenment, not the test or method used to achieve it. In this responsive openness to meaning, one breaks free of the delusory idea that truth is fixed and reality static.

Dong Zhongshu (195-115 BC)

Tradition hailed Dong Zhongshu as the 'father of Han Confucianism' because of his influential theories that posit a perfect congruence between divine and human realms kept in balance by the true king, who functions as mediator, moral exemplar and lawmaker. Undoubtedly the most famous exegete in the 'Gongyang' commentarial tradition to the Chunqiu (Spring and Autumn Annals), Dong is also credited by convention with the composition of the Chunqiufanlu (Luxuriant Dew of the Annals), though recent scholarship questions this attribution.

Major revisions in the conventional assessment of Dong Zhongshu are under way for several reasons. First, no early evidence supports the view of Dong as architect responsible for adapting pre-Qin Confucian thought to the needs of the centralized imperial Chinese state. Second, many theoretical innovations once tied to Dong can now be shown to either predate (sometimes by millennia) or postdate Dong, requiring a systematic reconsideration of Dong's distinctive contributions. For example, it now seems that Dong did not introduce either Five Phases theory or the Red-White-Black 'three ages' historical cycle into Confucianism. Third, the *Chunqiufanlu* is now more often seen as a composite text that may represent some 150 years of Gongyang scholarship, compelling scholars to begin the arduous task of isolating those passages assignable to Dong alone.

A review of all the extant material that is indisputably authentic shows the central importance for Dong of Heaven's relation to the king (see Tian). According to Dong, Heaven originates and embodies the impulse towards perfection in all things, then works through impersonal natural forces (specifically, the cycles of *yinqi* and *yangqi* (see Qi; Yin-yang)) to foster good rule by suasive virtue, thereby obviating the need for harsh punishments. A perfect congruence between the natural (*tiandi*) and human worlds means that change in one sphere produces comparable change in the other, so that human acts (especially those of the ruler and his immediate circle) influence cosmic harmony for good or for ill. This triadic correspondence is exemplified by the Chinese character for 'king', in which three parallel horizontal lines (for heaven-earth-man) are connected by a single vertical signifying the mediating 'king'. Implicit in Dong's simple vision are three important presumptions: (1) in cosmos and society, hierarchy is 'natural'; (2) rule by moral suasion can be perfectly effective because it partakes of the divine; and (3) unusual events (such as floods, droughts and fires) are to be analysed according to set rules imbedded in the *Chunqiu*, for they convey Heaven's encoded messages to the ruler.

Dong's thought may be reconstructed in three additional areas for which sufficient reliable material survives, namely his theories on law, human nature and economic policy. As jurist, Dong argued that the Han statutes should be modified in light of the Confucian principle of 'rectifying names' (see Logic in China §1; Confucian Philosophy, Chinese). In essence, Dong asserted that subordinates are obligated only to those superiors who have properly fulfilled their ascribed societal roles. (This assertion, of course, had important implications for legitimacy theory.) With regard to human nature, Dong believed that all humans at birth have the potential for both good and evil because Heaven endows both *yinqi* and *yangqi*; the transforming influence of the ruler and of ritual is needed if ordinary persons are fully to realize Heaven's intention. At one stroke, Dong thereby resolved the quarrel between Mencius and Xunzi over human nature and the origin of evil (see Xing). In his memorials on the economy, Dong urged the state to induce commoners to return to the 'basic occupation' of agriculture, while minimizing the gross inequalities in wealth that inevitably prove divisive to society. The ruler must insure his subjects' economic and physical security, and then moral education, if he is to fulfill his sacred obligations as Son of Heaven.

Internal contradictions abound in Dong's thought. For example, both Heaven and the sage seem at once omnipotent and sharply constrained, not only by great cosmic and historical cycles but also by the others' will to take the moral initiative. Thus it remains unclear which of several factors (such as the reigning monarch's character, receipt of the Mandate from Heaven or the operation of impersonal cycles) is primarily responsible for the state of the empire at any one time. Moreover, Dong's call for the total abolition of punishment for the common people is at odds with his firm belief that even sage-rulers provide less than perfect moral models for their subjects. Given such apparent confusion, Dong is often remembered best for three memorials urging the Han throne to reserve imperial patronage for Confucianism alone, since continued competition among contending ways of thought would preclude any attempts to forge a truly unified political and social system.

Dooyeweerd, Herman (1894-1977)

A Dutch philosopher and legal theorist, Herman Dooyeweerd challenged the Enlightenment ideal of autonomous rational thought and sought a religious foundation for philosophy. Religious self-knowledge, he contended, is the necessary condition of all knowing. Dooyeweerd proposed an elaborate ontology of physical and social reality based on the Christian doctrine of creation. His thought has been influential among Calvinists in The Netherlands, North America and South Africa.

Dooyeweerd was a Dutch neo-Calvinist philosopher and professor of law at the Free University of Amsterdam (1926-65). His most notable achievement was his lifelong effort to develop a distinctly Christian philosophy that included an epistemology which directly challenged modern Kantian rationalism and an ontology rooted in the Christian doctrine of creation. With D.H.T. Vollenhoven he founded the international Society for Calvinist Philosophy in 1935. His full philosophical statement, *A New Critique of Theoretical Thought*, anticipates a number of late-twentieth-century philosophical interests, including postmodern critiques of Enlightenment rationalism.

Dooyeweerd's work self-consciously builds on the late-nineteenth-century Dutch Calvinist revival movement inspired and directed by Abraham Kuyper (1837-1920). This neo-Calvinism had as its goal the full rechristianizing of Dutch culture and society, and proceeded from a strong Augustinian sense of spiritual antithesis between Christian and secular culture. For Dooyeweerd, as for Kuyper, all theorizing was rooted in religious presuppositions; the Enlightenment prejudice against prejudice was itself rooted in personal commitments. All thought is engaged and interested thought. Dooyeweerd's method of exposing the Enlightenment bias - his 'transcendental critique' - is one of his truly creative and significant accomplishments.

Unlike some Christian philosophers who attempt transcendent or external critiques of the pretended autonomy of modern thought and simply *assert* bias, Dooyeweerd tried to show that an immanent examination of thought itself reveals its religious presuppositions. Analogously to Kant's critical method, Dooyeweerd, who was decisively influenced by Neo-Kantian philosophy as well as by the phenomenology of Husserl, argued that a consideration of the necessary conditions of thought discloses a supratheoretical or religious starting point. Philosophy's concern about meaning directs all thought to questions of origin, and these questions cannot be answered by theoretical thought itself. This awareness of the boundary limits of theoretical thought forces the philosopher to confront the integrating capacity of the human ego or, in biblical terms, the heart. Self-knowledge is thus the basis of all epistemology, and pure presuppositionless rationalism is an impossibility.

Religion is thus the integrative reality of all thought. Dooyeweerd did not restrict his understanding of 'religion' to concrete, particular, historical religions, but, like Tillich (§4), understood it to be whatever human beings might give ultimate allegiance or value to. In his judgment, four religious, integrative 'ground-motives' dominate the history of Western thought: the Greek 'form-matter' motive, the medieval synthesis of 'nature-grace', the modern dialectic of 'nature' ('necessity') and 'freedom', and the biblical motive of 'Creation-Fall-Redemption'. For Dooyeweerd, as for neo-Calvinism, redemption is the restoration of creation.

Dooyeweerd's own ontology is rooted in Christian convictions about creation, particularly the conviction that creation is meaningfully diverse and structured by God's law. In Dutch his philosophy is called *Wijsbegeerte der Wetsidee* ('Philosophy of the Law-Idea'). Here Dooyeweerd also built on Kuyper's thought, this time on the notion of 'sphere-sovereignty': the idea that physical and social reality exhibits an irreducible diversity which is grounded in divine ordinances. While Kuyper utilized this doctrine primarily for political purposes (to free social structures such as the family and the school from the hegemony of the state), Dooyeweerd expanded it to a full ontology of 'modal aspects'. These modal aspects of created reality (including numerical, spatial, biotic, psychical, lingual, economic, jural-legal) are the investigative areas of the special sciences. The task of philosophy is to examine and explain how the modalities relate to each other. Dooyeweerd also developed a complex theory of whole 'entities' - termed 'individuality structures' - each of which in a unique configuration exhibits all the modal aspects.

Emphasizing the doctrine of creation also led Dooyeweerd to a rather positive attitude towards human culture and history. Strongly affirming Calvin's and Kuyper's doctrine of 'common grace' - God's non-saving favour towards all humanity - Dooyeweerd articulated a philosophy of history that was very appreciative of cultural development

(see Calvin, J. §§2-3). Cultural products and social institutions were perceived as organically unfolding and differentiating from their creational roots. Both this differentiation and cultural diversity are to be respected.

In addition to his native country, Dooyeweerd has had significant attention and influence in North America and South Africa. A ‘Dooyeweerd Center for Christian Philosophy’, which will concentrate on publishing Dooyeweerd’s works in English and stimulating the study of his thought, was opened at Redeemer College, Canada, in 1994.

Dostoevskii, Fëdor Mikhailovich (1821-81)

Dostoevskii, regarded as one of the world's greatest novelists, is especially well known for his mastery of philosophical or ideological fiction. In his works, characters espouse intriguing ideas about theology, morality and psychology. Plots are shaped by conflicts of ideas and by the interaction of theories with the psychology of the people who espouse them. Indeed, Dostoevskii is usually considered one of the greatest psychologists in the history of Western thought, not only because of the accounts of the mind his characters and narrators elucidate in detail, but also because of the peculiar behaviour betraying the depths of their souls. Dostoevskii is particularly well known for his description of the irrational in its many modes.

Deeply engaged with the political and social problems of his day, Dostoevskii brought his understanding of individual and social psychology to bear on contemporary issues and gave them a lasting relevance. His predictions about the likely consequences of influential ideas, such as communism and the social theory of crime, have proven astonishingly accurate; he has often been regarded as something of a prophet of the twentieth century.

His reputation rests primarily on four long philosophical novels - Prestuplenie i nakazanie (Crime and Punishment) (1866), Idiot (The Idiot) (1868-9), Besy (The Possessed, also known as The Devils) (1871-2) and Brat'ia Karamazovy (The Brothers Karamazov) (1879-80) - and on one novella, Zapiski iz podpol'ia (Notes From Underground) (1864). In his day, Dostoevskii was as famous for his journalistic writing as for his fiction, and a few of his articles have remained classics, including 'Mr. D-bov and the Question of Art' (1861) - a critique of utilitarian aesthetics - and 'Environment' (1873).

Dostoevskii's works have had major influence on Western and Russian philosophy. In Russia, his novels inspired numerous religious thinkers, including Sergei Bulgakov and Nikolai Berdiaev; existentialists, such as Lev Shestov; and literary and ethical theorists, most notably Mikhail Bakhtin. In the West, his influence has also been great. Here, too, his writings are repeatedly cited (along with Kierkegaard's) as founding works of existentialism. Perhaps because of a misreading, they influenced Freud and Freudianism. Directly and through the medium of Bakhtin, his ideas have played a role in the rethinking of mind and language. And his rejection of utopianism and socialism has been repeatedly cited in twentieth-century political debates and theories.

Dostoevskii's influence has been diverse and at times contradictory, in part because of the different genres in which his ideas are expressed. Not only the overall meanings of his novels but also the views of his characters, including those he meant to refute, have been attributed to him. Moreover, his essays sometimes express ideas at variance with his novels. Most recently, philosophical significance has been discovered not only in the content but also in the very form of his novels. Their odd plot structure has been shown to have implications for an understanding of authorship, responsibility and time.

1 Life

The son of a military surgeon, Dostoevskii grew up in a pious household to which he attributed his (rather tortured) religious faith. Celebrated at a young age for his early fiction, he became involved in a secret socialist society, the Petrashevskii Circle, which was infiltrated by the tsarist secret police. In 1849 he was arrested and, after spending months in prison, was sentenced to be executed, a sentence reduced at the last possible moment. The experience of mock-execution shaped both his sense of how the human mind works in extreme situations and his obsession with temporality. Dostoevskii then spent years in a Siberian prison camp, which he later described in his short novel *Notes From the House of the Dead* (1860-1), and several more years in internal exile before being allowed to return to European Russia. By his own account, his time in Siberia changed his views decisively. He rediscovered his religious faith and decisively rejected Western utopian socialism. Imprisonment itself led him to appreciate the importance of privacy and of individual choice, which he felt were rejected by socialists. Attending to the psychology of criminals, he came to see more clearly the irrational in everyone and rejected rationalist and utilitarian models of the psyche. Above all, his experience living among common people developed in him a deep distaste for the condescension of intellectuals who professed to save 'the people', whom they hardly knew. In the process, he came to reject the intellectuals' principal tool, abstract theory, as inadequate to the complexity of real human needs and motives.

Upon returning to Russia, Dostoevskii worked alternately as a journalist and a novelist. During this time, he suffered from a variety of misfortunes, including the epilepsy that first struck him in Siberia, compulsive gambling and constant indebtedness. He was forced to travel abroad to escape creditors and developed a deep distaste for the West. During his epileptic seizures, he experienced an extraordinary sense of universal harmony and of the cessation of all temporal processes, topics that appear prominently in his fiction (especially *The Idiot*) and fed his interest in time. His gambling led him to explore the human need for the radically uncertain and (a favourite problem) the nature of self-destructive behaviour performed by people who recognize it as such. His indebtedness and poverty, which reached extremes, sometimes forced him to write and publish his novels serially without an advance plan. Consequently, he was at times as uncertain as his characters about their destiny. He eventually made a virtue of this process, and by so doing discovered new ways to represent the openness of the future and the palpability of choice. He managed to transfer the excitement of the creative process to the novels themselves as he wrote them and as the readers read them.

His politics grew increasingly conservative, or rather anti-revolutionary, as he wrote novels about people possessed by extreme and radical ideologies. Although for most of his life Dostoevskii was severely sceptical about the possibility of a substantive philosophy of history, for a period of about two years (1876-7), he reversed his stance and imagined he had discovered the key to history and the signs of an imminent apocalypse, after which Russia would assume a messianic role and lead the world. These views appear in *Dnevnik pisatelia* (*A Writer's Diary*) (published intermittently from 1873 to 1881), a work that also experimented with turning a one-person periodical into a peculiar literary genre open to the contingencies of current events. Some articles written during this period, which occasionally included anti-Semitic diatribes, remain the greatest embarrassment to his contemporary admirers. Having come to his senses, he produced his greatest and probably most humane work, *The Brothers Karamazov*, shortly before his death in 1881.

2 Core ideas

Perhaps the core idea of Dostoevskii's works is human freedom. Famous as a psychological writer, he declared that he was not in fact a psychologist, if by that term one meant a person who regards human behaviour as governed by laws that make it in principle predictable. He described the historical process as not subject to laws and decisively rejected any theory guaranteeing progress (or any other outcome). In his theology, he insisted that the essence of Christianity was free choice, and so any religion that offered 'miracle, mystery, and authority' (a phrase in *The Brothers Karamazov*) as ways of allaying doubt were in fact anti-Christian. Thus uncertainty and striving without guarantees was essential, not detrimental, to Christian belief. For a similar reason, utopian politics promising to offer a final solution to ensure happiness would deprive us of our humanity, which is essentially a matter of effort, of choices that can be mistaken, and of processes without guaranteed outcomes.

Dostoevskii's novels consequently develop an antideterministic theory of time in which each moment possesses the potential for multiple futures. Whatever did happen at a given moment something else might have. In his articles on crime he argued, and in his novels he illustrated, that human intentions are often essentially processual: there may never be a moment when a decision is made, even subconsciously. Rather, a shifting and always incomplete process governs behaviour from moment to moment. In such cases, the ascription of an intention in the usual sense is a retrospective activity oversimplifying the facts. If a crime committed in this way could be repeated, the result might well be different, because the process allows for many possibilities at each moment of choice. One meaning of the image of the devil, who appears as a character in *The Brothers Karamazov*, is the personification of the forces introducing radical uncertainty into the world.

It followed for Dostoevskii that all ethical philosophy aspiring to iron-clad rules for moral action must be mistaken; for if such rules could be provided, action according to them would lack the quality of choosing the good in the face of uncertainty. Christ's image, not an abstract philosophy, must be our guide. The unknowability of the future also explains the fallacy behind utilitarian views of art. Dostoevskii agrees that art should be useful, but he contends that utility should apply to an uncertain future, when our purposes may be far from those of the present. Great art lasts because it is capable of affecting us in radically different times and places. Among the qualities that allow art to be unforeseeably useful is beauty.

Insisting on human unpredictability, Dostoevskii rejected utopian schemes because they were based on too great a

confidence in the needs of humanity as a whole and too little concern for individuals to make their own varying choices. Indeed, thinkers who place too much faith in an abstract theory are unlikely to recognize that people are essentially processual. Nevertheless, Dostoevskii believed that utopians with an unjustifiable faith in salvationist theories would likely seize control. As a result, he was probably unique among nineteenth-century writers in predicting that the twentieth century would be the era of what we have come to call totalitarianism, the features of which he described (especially in *The Possessed*) in remarkably accurate detail.

Dostoevskii's distrust of theory, especially his rejection of materialist and rationalist definitions of humanity, led him to another prescient prediction, this one pertaining to Western liberal societies. Whereas others typically assumed that increasing wealth and expanding freedoms would lead to reduced crime, Dostoevskii predicted the opposite. What would swamp liberal progress would be a decline in religious belief and the conviction that moral norms transcend utilitarian purposes. The more people come to accept that good and evil are merely social constructs, the less restraint they will feel. If God is dead, then all is permitted, as Ivan Karamazov says (in *The Brothers Karamazov*). No amount of law enforcement could ever compensate for the inner conviction that crime is simply morally wrong in the eyes of God or from the perspective of some transcendent value. Moreover, the very theory that crime is merely the product of the social environment is itself part of the social environment. Its acceptance is bound to increase crime. Dostoevskii repeatedly performs this self-reflexive act on theories, a move that fits well with his novelistic technique of examining ideas by their lived consequences.

3 Major works before *The Brothers Karamazov*

Zapiski iz podpol'ia (*Notes From Underground*) (1864) consists of two parts, a paradoxical philosophical diatribe by the narrator and a series of reminiscences of his earlier life. Part I argues, and both parts illustrate, the complexity of psychological processes that transcend all theories presuming human rationality. His critique of all rational choice models can still stand as a useful corrective today. These models fail for two important reasons. First, they are false to actual experience. The underground man cites witty examples from daily life and history that only the most tortured or tautological reasoning could subsume under a model of rationality. Second, the most important human preference does not resemble the others and cannot be listed along with them: the desire to choose unpredictably. Any model that makes human action in principle predictable deprives us of our very selves. Satisfy all our desires, and we will desire to harm ourselves, simply to show that we are people and not 'organ stops' or 'piano keys'. That is, our greatest desire is a meta-desire, a longing to desire unpredictably. That is the source of the underground man's 'spite', a concept to which he gives metaphysical significance.

In the course of his tirade, the underground man also rejects the existence of any historical laws and all models discerning an inner rationality to history. Alluding to Hegel, he observes: 'The only thing one cannot say [about history] is that it is rational'. Polemicizing with Buckle and liberal faith in a law of progress, he observes that civilization has given humanity more efficient and crueller ways to kill and torture each other (another passage anticipating the twentieth century). Thinkers invent historical and social laws because they have decided in advance that only such an approach is truly scientific, which is ironic because science involves fidelity to the facts. 'But man is so fond of systems and abstract deductions that he is ready to distort the truth intentionally, he is ready to deny what he can see and hear just to justify his logic' ([1912-20] 1960: 21).

If determinism were correct and if scholars really could know the true laws of history and psychology, then human life would turn into 'extracting square roots' and behaving according to 'a table of logarithms'. Life would then be simply a finished product, but it can be meaningful only as a process. All utopian schemes, with their image of a finished and perfected world, would, if realized, become prisons, houses of the dead. Nevertheless, Dostoevskii also rejects the underground man's way of opposing such rationalism by pure spite. Spite, the novel demonstrates, also has its own iron-clad, if perverse, logic. Real freedom cannot be found simply by inverting determinism, as the underground man does. Rather, the work implies, it demands the Christian concept of humanity as free and the self as developing in relation to others.

In *Crime and Punishment* (1866), Dostoevskii explores the psychology of an intellectual who wants to live according to various theories justifying murder. The novel shows each of these theories to be inadequate to the way people actually live and feel. Indeed, the theories motivating the hero contradict each other, as one justifies killing as moral on utilitarian grounds while another denies that morality is anything but an empty social construct. Moreover, the hero finds himself unable to account, after the crime, for his decision to commit it, the reason being

that he never actually made a decision. He was, rather, possessed by a state of mind that guided him processually, moment by moment, in a dream-like state. Taken as a whole, the novel refutes ideology - not just particular theories, but the ideological cast of mind itself - by psychology.

One of the hero's theories is that humanity is divided into two groups, a majority of ordinary people who serve as mere breeders and a minority of innovators who have the right to transgress all moral codes. Dostoevskii suggests that the desire to be a superman in this way is typical of any intelligentsia that takes its theories too seriously. Even, or especially, if such schemes promise to make people happy, they will lead to killing and cause more harm than good. But they exert an almost irresistible appeal for intelligentsias.

The Idiot (1868-9) written without an advance plan with the author discovering the course of events along with his characters, may be taken as a kind of thought experiment. The author creates a perfectly good man and sees what effect he would have on real people, whose psychology includes the perverse and irrational as well as more normal human motivations. People often react to the Idiot's goodness by feeling resentful at their own moral inferiority, which leads them to still worse behaviour. The result is that, because of his very goodness, he destroys both himself and almost everyone around him.

In effect turning its own processual composition into a theme, this novel also explores the nature of time, arguing (in what is probably the work's most famous passage) that 'Columbus was happy not when he had discovered America, but when he was discovering it.… It's life that matters, nothing but life - the process of discovering, the everlasting and perpetual process, not the discovery itself, at all' ([1912-20] 1962: 21).

The Possessed, often considered the greatest European political novel, explores the mentality of revolutionaries and fashionable liberals. Almost as critical of liberals as of radicals, Dostoevskii saw the former as the progenitors of the latter, even though they are often horrified by them. Both share the mentality of the intelligentsia, which views itself as entrusted with the salvation of humanity. The novel criticizes the tendency of utopians to reason down from abstract principles, which leads them to absurd but dangerous social conclusions. Arguably the most quoted line of the novel belongs to one radical theoretician: 'Starting from unlimited freedom, I arrive at unlimited despotism'. In a passage that seems to anticipate the Chinese Cultural Revolution, the novel attacks radical egalitarianism as an ideal. Under socialism, one revolutionary declares, 'All are slaves and equal in their slavery… the great thing about it is equality… Cicero will have his tongue cut out, Copernicus will have his eyes put out, Shakespeare will be stoned' ([1912-20] 1963: 424).

4 *The Brothers Karamazov*

More extensively than any other work of Dostoevskii, *The Brothers Karamazov* explores the nature of Christian truth. Developing an idea in *The Idiot*, Dostoevskii demonstrates that goodness consists of small, kindly actions, rather than great and heroic deeds. Small actions may have a concatenating effect no one can foresee. Evil, too, is conceived as consisting primarily of day-to-day actions. Thus in one chapter, when the devil appears as a character, he is not grand, Satanic and alien, but ordinary and banal. This 'petty devil' is one of Dostoevskii's most famous creations.

The height of Dostoevskii's achievement appears in a sequence of three chapters, in which the intellectual brother, Ivan, tries to seduce his pious younger brother, Alësha, from religion by refuting Christianity on moral grounds. It is remarkable that these arguments, coming from the pen of a Christian author, have often been considered to be the strongest pages ever written against faith. In 'Rebellion', Ivan contrasts all conceivable theodicies with the reality of innocently suffering children. Ivan has also composed 'The Grand Inquisitor', a story in which Christ returns to earth during the Spanish Inquisition and is arrested by the Grand Inquisitor, who contends that Christ should have accepted the temptations of the devil just as (he says) the Catholic Church actually has. The Inquisitor reasons that people do not want to be free, only to think they are free. They can be happy only when their consciences are held by others and their choices are made for them, so they will not feel guilt or regret whatever happens. The Inquisitor's ideals evidently represent socialism as well as Catholicism, two apparently antagonist movements that, in Dostoevskii's view, were really the same because they share an anthropology.

Christ never replies to the Inquisitor, and the Inquisitor's arguments appear irresistible, and yet the reader, for reasons that are hard to specify, adheres all the more strongly to the Christian ideal of freedom. Ivan has 'refuted' God the Father in 'Rebellion' and God the Son in 'The Grand Inquisitor', but he has unwittingly adhered

to the Holy Spirit in ‘The Brothers Make Friends’. Here his sheer love of ‘the sticky green leaves that open in the spring’ expresses a love of God’s world. As elsewhere in the novel, Dostoevskii’s point is that faith comes not from doctrine but from how one lives moment to moment. It is not doctrine that leads to faith, but faith, born of good living, that may lead to acceptance of doctrine, which is not the content of true religion but its expression.

The novel’s plot turns on Ivan’s theory that moral responsibility, if it exists at all, pertains only to actions, not to wishes. Ivan will do nothing to harm his thoroughly noxious father, but ‘in my wishes I reserve myself full latitude’. When his father is killed, Ivan comes to feel guilty precisely for wishing his father’s death. He is right to do so, because the novel demonstrates that most evil happens indirectly, because a climate of evil is created by our evil wishes. In such a climate, crime is bound to happen one way or another. The proximate cause of such crimes is less important than the climate. Because all of us indulge such wishes, ‘everyone is responsible for everyone and for everything’, as the novel’s holy Father Zosima contends ([1912-20] 1950: 244). This logic also explains why the devil, as the personification of evil, is thoroughly ordinary.

We are reminded of the Sermon on the Mount, where Jesus says that we are responsible for our wishes. In this way, the novel demonstrates the truth of the Gospel psychologically. Ivan’s doctrines, whatever their strength as dialectic, run counter to the human spirit. Of course, Dostoevskii’s psychological ‘proof’ of Christianity does not demonstrate the existence of God or the doctrine of the Trinity. But it does show that faith is grounded not in some philosophical propositions, but existentially and anthropologically, in the depths of our being.

Like *Notes From Underground* and *The Possessed*, *The Brothers Karamazov* explores the psychology of ‘the insulted and the humiliated’, a trade mark theme of Dostoevskii. If one understands this spiritual state, one will see that those afflicted with the psychology of their own victimization are precisely the ones who understand best how to inflict pain on others and who are most likely to seek revenge by doing so. It follows that such people, for all their claims to the moral high ground, are the last ones in whom one should entrust political power.

5 Time, form and ethics

Deeply concerned with describing time as open, Dostoevskii remained suspicious that the well-structured plots of traditional novels implicitly endorse determinism or fatalism. The problem is that in these works everything fits and events take place not only because of prior causation, as in life, but also in order to fit a pattern visible when the work is over. Thus, contingency is ruled out. Dostoevskii therefore developed a method of writing ensuring that the reader senses at each moment that whatever happens, something else easily could have. Time therefore becomes a field of possibilities. Nothing is tending to a pregiven ending - which, in fact, Dostoevskii himself sometimes did not know. The unstructured quality of some of his works, which often contain numerous loose ends, results from this technique. On the other hand, the extraordinary suspense of his novels derives from this method of representing time the way it is experienced in life, as truly open. Thus the very form of Dostoevskii’s novels became an instrument of his argument for freedom in an open world containing ‘an infinite multitude of ramifications’ (as one character in *The Idiot* says) and countless possibilities, shaped by chance and by our own actions.

The sense of open time is also reflected in Dostoevskii’s ethical tenets. If people are fundamentally free, then they always have the ability to be surprising. It followed for Dostoevskii that one thing we must never do is treat others as if they were fully known quantities, as if we could be sure what they are going to do, as the various schools of psychology in principle do. In rejecting determinism, materialism, nihilism, historicism and psychologism, while rethinking the nature of narrative art, Dostoevskii explored the meaning of human freedom.

Double effect, principle of

'Double effect' refers to the good and bad effects which may foreseeably follow from one and the same act. The principle of double effect originates in Aquinas' ethics, and is supposed to guide decision about acts with double effect where the bad effect is something that must not be intended, such as the death of an innocent person. The principle permits such acts only if the bad effect is unintended, not disproportionate to the intended good effect, and unavoidable if the good effect is to be achieved. The principle has wide relevance in the moral evaluation of acts which have foreseen double effects. Controversy arises over the identification of the agent's intention in difficult cases, and over the use of the principle to resolve issues such as abortion, euthanasia, the use of pain-relieving drugs which hasten death, self-defence, and the killing of certain sorts of non-combatants in war.

1 The role of the principle

The principle, or doctrine, of double effect is important in the application of moral theory to practical cases. The principle asserts the moral relevance of a distinction between those effects of our acts which are intended and those effects which are foreseen but unintended. Sometimes in acting for the best we bring about an unavoidable yet foreseen bad effect which is not part of what we are aiming to achieve. For instance, a doctor prescribes chemotherapy for cancer, knowing that this treatment also causes hair loss; a driver whose brakes fail swerves in order to avoid a group of children on a pedestrian crossing, foreseeing that the car will hit someone standing at the side of the road; a teacher fails an essay that does not deserve to pass, knowing that the student will be upset. 'Double effect' refers to the two foreseen effects of acts such as these: the good effect (eliminating cancer, saving lives, maintaining academic standards) which the agent intends, and the bad effect (hair loss, injuring or killing someone, causing distress) which the agent foresees but does not act in order to bring about.

Many acts with double effect can be characterized as instances of bringing about the lesser of two evils: opting for what is morally more important, at the expense of foreseeably causing a bad effect which is outweighed by the intended good effect. Where the foreseen bad effect is itself morally serious (such as the death of an innocent person), the principle of double effect holds that the bad effect must be unintended: it must not be what the agent aims to achieve in the circumstances nor a means to bringing about the intended good effect. The principle could permit the driver to swerve in order to avoid hitting the children on the crossing, even though the person standing at the side of the road is thereby seriously endangered. But the principle does not permit an agent to kill an innocent person as a means of saving others; the driver must not aim to kill the person at the side of the road as part of a plan.

2 Origin, development, conditions and application

The principle is traceable to Aquinas' justification, in *Summa theologiae*, of homicide in self-defence. Aquinas held that a private person must never kill anyone intentionally; hence his appeal to 'double effect' in justifying foreseen killing in self-defence. The use of lethal force in self-defence has two foreseen effects: saving oneself (good effect) and the death of the aggressor (bad effect). Aquinas maintained that, provided one's intention is only to use necessary and proportionate force in warding off an unjust attack, the aggressor's death is unintended.

The principle of double effect has been developed subsequently as a general precept of nonconsequentialist ethics. The principle is central to absolutist moral theories which hold that some intended acts are always intrinsically evil and that it is never permissible to use an evil means to achieve a good end. The combination of these two tenets can make moral decision very difficult in some cases in which agents will foreseeably bring about a serious bad effect whatever they do. If the driver whose brakes fail does not swerve, the children on the crossing will probably be killed; if the driver does swerve, the person at the side of the road will probably be killed. As a guide to decision in such cases, the principle holds that under strict conditions it is permissible foreseeably to bring about an effect of a type that it is never permissible to intend. These conditions are: that the act itself (in this case, swerving the car) be morally good or indifferent; that the bad effect (killing the one person) be an unavoidable, unintended effect of the act which also achieves the good effect (saving the children); and that the good effect be sufficiently weighty to warrant causing the bad effect. The last condition, proportionality, must always be taken into account. The agent's good intention, and the fact that the bad effect is unintended, are on their own insufficient to permit foreseeably causing serious harm. Evaluation of the relative seriousness of good and bad

foreseen effects is sometimes reasonably straightforward, but sometimes can be difficult.

The distinction between intended and unintended effects is also more widely invoked as part of nonabsolutist, nonconsequentialist moral theories which hold that the agent's intention is important to the moral evaluation of acts which have both good and bad foreseen effects.

3 Criticisms, difficulties and further applications

Critical discussions of the principle focus on the distinction between incidental and intended effects and on its relevance to practical moral problems. According to the principle, a foreseen bad effect is unintended provided it is incidental to what the agent aims to achieve in the circumstances and to the means of bringing about the intended good effect. If we return to the example of the swerving car, incidental and intended effects are distinguished easily: the driver does not swerve the car in order to hit the person at the side of the road, but in order to avoid hitting the children; the children are saved not by that person's being harmed but by the car's swerving. Exponents of the principle often invoke the so-called 'test of failure' in maintaining that particular foreseen bad effects are incidental both to the agent's aim and to the means of its achievement in the circumstances. This test, which Duff (1990) points out must be applied in the light of the agent's beliefs at the time of acting, asks: would agents fail to achieve what they intend if, contrary to expectation, the foreseen bad effect does not occur? To this question, the swerving driver can answer sincerely, 'No, I intend to harm as few people as possible; my aim will be achieved if the person at the side of the road somehow escapes injury.' However, both the identification of the agent's intention and the distinction between the foreseen good and bad effects, on which the principle relies, can be difficult. For instance, if I can stop an aggressor only by shooting through an innocent person whom the aggressor is using as a shield, do I intend harm to the innocent shield or not? If the 'test of failure' is plausibly to identify particular foreseen bad effects as incidental, such effects must be distinguishable in a defensible way both from the good effect and from the means of achieving it in the circumstances. As has been suggested by Foot (1967), the principle cannot allow one to maintain that one does not intend to kill someone, but only to blow them to pieces. The characterization of the agent's intention in the context of some traditional applications of the principle, such as termination of ectopic pregnancy and homicide in self-defence, is problematic. These important difficulties have been addressed by both advocates and critics of the principle.

The principle of double effect is relevant to critical legal thinking about, for instance, the mental element of murder, and the appropriateness of the defence of necessity in cases of justified risk taking. In paradigm acts of double effect the agent foresees both the good and bad effects as certain or highly probable. The distinction between intended and foreseen effects, however, is also applicable to acts of justifiable risk taking, in which the good and bad effects are incompatible possible outcomes; in such cases the bad effect can even be the more likely to occur. For example, a surgeon might justifiably operate in a desperate attempt to save someone's life, foreseeing that the surgery or its effects may well kill the patient; a parent might justifiably throw a child out of a burning building as its only hope of survival, realizing that the fall may well kill it.

Doubt

Doubt is often defined as a state of indecision or hesitancy with respect to accepting or rejecting a given proposition. Thus, doubt is opposed to belief. But doubt is also contrasted with certainty. Since it seems intelligible to say that there are many things we believe without being completely certain about them, it appears that we may not have a unitary concept of doubt.

Although doubt is often associated in philosophy with scepticism, historically the relation between the two is complex. Moreover, some philosophers deny that sceptical arguments have any essential connection with inducing doubts.

Sceptical doubts, as philosophers understand them, differ from ordinary doubts in their depth and generality. We all have doubts about some things. But the philosophical sceptic wonders whether we ever have the slightest reason to believe one thing rather than another. However, the reasonableness of such doubts - and even their intelligibility - remains controversial. The various attitudes philosophers adopt with respect to the status of sceptical doubts characterize the main approaches to epistemological theory.

1 Doubt, belief and certainty

Dictionaries typically run together concepts such as indecision and hesitancy, contrasting doubt with both belief and certainty. But as we can evidently believe something without being certain about it, it seems that our concept of doubt itself may not be clear-cut. It is tempting to speculate that this seeming duality is a result of competing epistemological traditions: an older tradition that identifies knowledge with demonstrative knowledge, hence with rational certainty (see Certainty), and a newer tradition for which probabilistic justification is sufficient. But it is also worth noting that ‘belief’ has become a term of art. Outside philosophy, reference to a person’s ‘beliefs’ is likely to mean their fundamental convictions and not just anything they might be said to accept. Even in philosophy, much discussion of doubt has had in the background questions about religious faith, which might also contribute to a dictionary’s associating belief with certainty.

Thinking of belief in the modern philosopher’s wide sense, how should we understand the relations between belief, certainty and doubt? One question concerns whether belief is an all-or-nothing matter or whether it admits of degrees. For Bayesians, although there are some beliefs to which we assign the highest possible strength, most belief is partial (see Probability theory and epistemology). So from a Bayesian standpoint, although there is a natural contrast between doubt and certainty, doubt is not opposed to belief.

What if we insist that belief is all-or-nothing? It is widely held that there are two types of certainty: subjective (which applies to persons), and objective (which applies to propositions). So we might say that, when we assent to propositions on inconclusive evidence, we recognize *them* to be less than certain but *we* have made up our minds. To assent is to eliminate subjective uncertainty - that is, doubt.

This is not conclusive. Even if belief is all-or-nothing, some beliefs are more firmly rooted than others. If we think of these degrees of entrenchment as degrees of subjective certainty, ‘doubt versus belief’ and ‘doubt versus certainty’ will draw different distinctions. In reply, we might say that a shallowly rooted proposition is one I regard as doubt*ful* - that is, open to reasonable doubt - which does entail its being doubt*ed*. But it seems equally natural to say that this would be something I accept, while still having doubts about it. Our concept of doubt just may not be unitary.

2 Philosophical doubt

In philosophy, doubt has often been connected with scepticism. However, for the ancient sceptics, suspension of judgment is not doubt but its cure (see Pyrrhonism). This makes sense if we think of doubt as an *uncomfortable* state of indecision, the discomfort arising from a persisting desire to decide. If systematic suspension of judgment attenuates this desire, it eliminates the anxiety of doubt.

Scepticism can vary in strength. A fairly weak form of scepticism denies that anything is certain (doubt versus certainty again). By contrast, radical scepticism attacks the possibility of our being able to justify a belief to even the slightest degree. Scepticism can also vary in scope: it can be narrowly focused; it can pertain to certain broad

classes of beliefs (for example, all beliefs about the external world); it can be universal. The sceptic's 'philosophical' doubts are distinguished from ordinary doubts by both their unusual depth and their generality: they extend to matters that are not ordinarily doubted, or even considered open to doubt.

Philosophers have been interested mainly in *reasonable* doubt - doubt for which one has a good reason - and particularly with the *limits* of reasonable doubt. Since sceptical arguments suggest that the scope for reasonable doubt is much wider than we normally suppose, exploring the limits of reasonable doubt is very much a matter of exploring the limits of scepticism.

The fundamental argument for universal scepticism goes back to the classical Greek sceptics and centres on a deadly trilemma: that any attempt to justify a belief leads to a vicious regress, reasoning in a circle, or reliance on brute assumptions. This argument would be defeated if we could identify beliefs which could not rationally be doubted. The quest for such 'basic' beliefs is characteristic of foundationalism (see Foundationalism). However, philosophical opinion has moved steadily away from regarding any beliefs as strictly indubitable. Contemporary foundationalists mostly favour a more modest conception of basic beliefs, according them some intrinsic but defeasible credibility (see Knowledge, defeasibility theory of).

It would be desirable to defeat universal scepticism without resort to the idea of intrinsically credible basic beliefs. Beliefs that can plausibly be accorded this privileged status tend to be unambitious with respect to their content, which makes problematic their adequacy as a basis for reasonable belief. Thus foundationalism meets one kind of scepticism only at the cost of threatening us with others. Consider scepticism with respect to knowledge of the external world. The argument for this form of scepticism famously occurs in Descartes, who claims that, since his entire experience of the world could be a kind of systematic hallucination induced by an evil demon, all his beliefs about external reality can reasonably be doubted, at least until he sees how the possibility of such deception can be eliminated (see Descartes, R. §4). But the thought that experiential knowledge underdetermines what it is reasonable to believe about the world makes a sceptical point only if, in the last analysis, experiential beliefs are intrinsically 'epistemologically prior' to beliefs about the world. Generalized doubts depend on generalized relations of justificatory dependence.

If this is correct, 'Cartesian' doubts depend essentially on foundationalism. However, many philosophers, including Stroud (1984b) and Nagel (1986), deny that any sceptical arguments depend on such highly specific and controversial epistemological commitments. They see scepticism as 'natural' or intuitive in the sense of arising out of the most ordinary and everyday epistemological considerations; but this conception of scepticism is more difficult to defend than is often thought.

Since by ordinary standards the error-possibility Descartes cites as a ground for doubt is remote, how reasonable are his doubts? The answer to this question is complicated by the fact that the 'reasonableness' of doubt is affected by other than purely epistemological considerations. For example, in a situation where the costs of making a mistake are very high, it might be reasonable to remain in doubt about something even though in possession of evidence that would ordinarily be considered sufficient (see Contextualism, epistemological). This suggests a defence of the reasonableness of doubts based on the remote error-possibilities that figure in sceptical arguments. True, such possibilities are not to be taken seriously in ordinary contexts of inquiry. But Descartes' project - a systematic, reconstruction of human knowledge from the ground upwards - is far from ordinary. This project, which requires setting aside all practical concerns, enforces a higher standard of certainty than would be reasonable in everyday contexts. However, this argument, because of its emphasis on certainty, is not clearly a defence of the reasonableness of radical scepticism, which is the most interesting type.

Hume claims that sceptical 'doubts' are not just unreasonable but entirely fictitious. According to Hume, no one seriously doubts that there is an external world because it is psychologically impossible to doubt such 'natural' beliefs. Having a theoretical answer to scepticism is neither here nor there. (This line of thought has recently been endorsed by Strawson (1985).) There are two replies. One draws on the point made above: that sceptical doubts arise only in the context of a distinctive kind of theoretical inquiry. To be sure, no one ordinarily doubts the things the sceptic questions; but why does this show that they are always and everywhere immune from doubt? Even Hume admits to being overwhelmed by sceptical doubts when he withdraws from ordinary concerns and reflects on their rational basis. The second reply (see, for example, Harman 1973) defends the interest of sceptical arguments by denying that they have any essential connection with doubt. We do not need to refute the sceptic to

assuage anyone's actual doubts. Rather, the hope is to learn something about knowledge by seeing how such arguments go wrong. At bottom, these two replies are not all that different. Not even Descartes claims to be able permanently to strip himself of his ordinary beliefs. His doubting them in the course of philosophical inquiry consists in not taking them for granted. In this sense, even the most purely methodological sceptic may be said to doubt his common-sense convictions.

3 Philosophical doubt (cont.)

Highlighting the context-sensitivity of sceptical doubts raises interesting and unresolved issues about the relationship between the results of philosophical reflection and everyday practices of inquiry. The traditional view has been that philosophical reflection brings into view fundamental epistemological facts which 'practical' concerns lead us to ignore. So, if sceptical arguments are irrefutable, we have discovered, under the conditions of philosophical inquiry, that no belief about, say, the external world can be adequately justified. But if philosophical inquiry imposes extraordinary constraints on knowledge and justification, we may only have discovered that knowledge is impossible under the (self-imposed) conditions of philosophical inquiry.

There is a deep disagreement here. Is sceptical doubt rooted in fundamental, context-invariant facts, like the supposed epistemological priority of experiential beliefs over beliefs about the world, so that it points to something about knowledge in general? Call the view that it is 'epistemological realism' and note that it is far from obvious that ordinary epistemic practices commit us to such a conception of justificational relations. Or does what it is reasonable or even possible to doubt depend on contextually variable factors, most notably the kind of inquiry in which we are involved, so that sceptical doubt may be an artefact of a certain conception of epistemological investigation, hence (again) not at all 'natural'? This much is sure: if doubt is strongly contextually constrained, it is not a merely psychological fact that doubts which seem so compelling in the study dissipate in the street.

Traditional epistemological theories such as foundationalism and the coherence theory take sceptical doubts at face value and try to provide reassurance (see Knowledge and justification, coherence theory of; Foundationalism). But some philosophers question the very intelligibility of universal doubt. This results from philosophy's having taken 'the linguistic turn'. Whereas language used to be regarded as a medium for the communication of thought, which was conceived to exist independently of language, the currently dominant view is that language is a *vehicle* of thought. This conception leads many philosophers to see an essential connection between truth and meaning: what our words mean - hence what thoughts we have - is a function of what sentences we hold true (see Charity, principle of). To entertain all the thoughts we currently have while universally doubting their truth may not be as straightforward as once was supposed. Such ideas mesh nicely with a contextualized conception of doubt and justification. *Anything* may be dubitable, but not *everything* at once. We can keep doubt as a spur to inquiry without worrying that it is in permanent danger of getting out of hand.

Doxography

*Doxography is a term describing the method of recording opinions (*doxai*) of philosophers frequently employed by ancient Greek writers on philosophy. It can also refer to texts or passages consisting of such accounts. The ancient tradition of doxographical writing finds its origin in the dialectical method of Aristotle and Theophrastus. Later works by authors such as Aëtius and Arius Didymus record much valuable material on ancient philosophers, although usually with little analysis or argumentation. Doxographical passages are also found in other ancient philosophical works, usually as a prelude to the discussion of a theme.*

The term ’doxography’ is derived from the neologism *doxographus* introduced by the German scholar Herman Diels. Literally it means ‘writer of opinions (*doxai*)’. In his great work *Doxographi Graeci* (1879) Diels collected various ancient documents which summarize the philosophical doctrines of ancient philosophers (particularly in the area of natural philosophy). He meant the term to contrast with *biographus*, ‘writer of lives’, although in practice it is difficult to make an absolute distinction between the two kinds of writings (see Diogenes Laertius).

If we examine the documents collected by Diels and others more closely, we can see that at least three different kinds of writing are found:

(1) In the so-called ‘Placita’ literature the organizing principle is systematic. Groups of *placita* (views) or *doxai* (opinions) are collected on particular subjects, each attributed to a philosopher or school: for example, ‘Plato declared that the cosmos is unique. Democritus and Epicurus affirmed that there are infinite worlds’, etc. The most famous example of such a collection is by Aëtius, first reconstructed by Diels on the basis of a Pseudo-Plutarchean *epitome* and extracts preserved by the anthologist Johannes Stobaeus.
(2) In the so-called ‘On the Schools’ (*Peri haereseōn*) literature, the doxographical information is collected in order to present the thought of a school of thought (for example, the Stoa) or an important philosopher (for example, its founder Zeno). Good examples of such doxographies are found in the surviving fragments of Arius Didymus and in Diogenes Laertius.
(3) A third genre that is related to doxography is the so-called ‘Successions’ (*diadochai*) literature, in which the generations of philosophers are linked to each other by way of a teacher-pupil relation, both prior to and during the development of the philosophical schools in the Hellenistic period: for example, Anaximander was the pupil of Thales in the so-called Ionian succession. The best surviving examples are the works on the Academy and the Stoa found in the library of Philodemus at Herculaneum. Although in these works relatively little information is given on the doctrines of the philosophers, the principle of the succession is a feature shared with other doxographical accounts.

Apart from these specific doxographical writings, doxographies are frequently found in authors when they deal with particular philosophical topics. A famous example is found in Cicero’s work *On the Nature of the Gods* (I 18-41), which begins with a long doxographical survey of theological opinions inserted in a piece of Epicurean polemic (see Cicero §3). This reflects the origin of the practice, which, as Mansfeld (1992) has shown, is to be located in the dialectical method introduced by Aristotle. When embarking on the examination of a philosophical theme, Aristotle often first collects and examines the so-called *endoxa* (reputable opinions). For example at the beginning of *On the Soul* (I 2.403b20) he states: ‘For our study of soul it is necessary, when formulating the problems of which in our further advance we are to find the solutions, to summon the opinions (*doxai*) of our predecessors, so that we may profit by whatever is sound in their suggestions and avoid their errors’.

Aristotle’s practice was continued and extended by his colleague and successor Theophrastus (§8). Especially influential appears to have been his large collection of *Physical Opinions* in eighteen books, which gave a systematic presentation of the views of the philosophers up to Plato on natural philosophy. This lost work is thought to have been the source of much material in later doxographical works and accounts, although the precise contours of its influence have proved difficult to trace.

From its origins in the Peripatetic school, the doxographical method became widely used in ancient philosophical writings. It is particularly common in Patristic sources, since it gives a quick overview of pagan thinking. A defect of doxography is that in the course of time it tends to become rather schematic, eschewing both argument and

analysis, and concentrating chiefly on the juxtaposition of views or on a thin skeleton of doctrine. This lack of argumentation has given the doxographical tradition a bad name. Nevertheless it should be recognized that it has distinctive methods (especially involving the use of disjunction and diaeresis), which give us important insights into the way that ancient philosophers handled their own history. Moreover it has preserved a great amount of invaluable information on the views of philosophers which would otherwise have been lost.

In modern scholarship on ancient philosophy the term ‘doxography’ is also often used in a broader, less technical sense. In such cases it describes all forms of presentation of philosophers’ views by means of summaries without direct reference to the philosopher’s own words. Because this broader usage invites confusion with the doxographical tradition proper as described in the main body of this article, it is not to be recommended.

Du Bois-Reymond, Emil (1818-96)

Emil du Bois-Reymond conducted pioneering research in electrophysiology which established him as a major figure in German science in the second half of the nineteenth century. His influence extended further through his more general writings in politics and philosophy of science, in which he argued for theoretical restraint and for the recognition that certain problems (for example, the mind-body problem) fell beyond scientific modes of inquiry and explanation.

Du Bois was born in Berlin and educated there in medicine and physiology. His distinctions in experimental science resulted in election to the Berlin Academy of Sciences; he was later honoured as its perpetual secretary from 1867. Holder of the chair of Physiology at Berlin from 1858 and co-editor of *Archiv für Anatomie* from 1857 to 1877, du Bois exercised great influence in the biological sciences throughout the second half of the nineteenth century.

Du Bois is of interest as a result of two distinguishable but interconnected projects. The first is that body of research and theory concerned with basic principles in neurophysiology. The second is his more general and accessible writings in philosophy of science. It was through his standing within the scientific community that these latter productions came to enjoy great authority.

At the start of his career, Du Bois was a researcher in Johannes Müller’s laboratory, as one of a group of young scientists who in a matter of years would become leading figures, namely Carl Ludwig,Ernst Brücke and Herman von Helmholtz. These four entered into something of a pact: they were to reject any theory in biology that was not grounded in the basic sciences of physics and chemistry. The graduation thesis du Bois had submitted to the Berlin faculty reported the results of his research on electric fish. In 1841, Müller passed along Carlo Matteucci’s recent ‘Note sur les phénomènes électrique des animaux’ (*C.R. Acad. Sci.*, Paris, 1841, (13): 540-), in which Matteucci had shown that electrical currents could be recorded between a point on the surface of a muscle and one deep within it. Taking this as his starting point, du Bois proceeded to investigate electrophysiological phenomena under a wide variety of conditions, publishing the results and their theoretical implications in his influential two-volume *Untersuchungen über Thierische Elektricität* (*On Animal Electricity*) (1848-9). In later years, du Bois criticized Matteucci’s methods and resented his failure to cite those of du Bois’ studies on whichMatteucci’s work depended. Du Bois explained his findings in terms of a wave of polarization created by what he called ‘electromotive molecules’ of positive and negative charge. He scrupulously avoided taking a firm position on the actual physical nature of these hypothetical entities, stating only that they should be understood as ‘foci of chemical change’. Subsequent developments in neurophysiology disconfirmed some of the details of du Bois’ theory, but his general perspective was redeemed.

As a statesman of science eager to establish its proper place within the larger contexts of culture and thought, du Bois contributed two books of considerable interest and importance. In his *Über die Grenzen des Naturerkennens (On the Limits of the Knowledge of Nature)* (1872) a modest and restrained positivism can be identified, the echo of the early pact barely audible. He acknowledges the inability of experimental science to settle issues of an essentially metaphysical nature, and is prepared to accept the possibility that even certain natural phenomena will never disclose their most fundamental principles. The mind-body problem illustrates this well. This problem, as he understood it, exemplifies the general problem of reconciling different ‘substances’. A distinguished neurophysiologist, du Bois fully appreciated the dependence of mental life on the integrity and functional capacities of the nervous system. But on the question of just how these functions do give rise to mental life - just how physicochemical processes influence, determine or regulate mental life - du Bois offered his famous one-word answer: *‘Ignorabimus!’* (‘We will be ignorant!’). It is interesting that du Bois would illustrate the general problem further by noting the (substantial) difference between matter and energy.

A later edition of this work, published in 1880, includes his *Die Sieben Weltrathsel (The Seven Riddles of the Universe)*. Here du Bois defends the overarching perspective of the scientist, which includes not only the commitment to disinterested and objective inquiry, but also the modesty of the fallibilist. In acknowledging at once the power and the limits of scientific knowledge, he preserved room for philosophy to bring its quite different methods of analysis and inquiry to bear upon vexed questions, even as he liberated science from the burden of

having to explain what in the end may well be inexplicable.

Du Bois also expressed himself publicly on matters of political and social importance. On the Franco-Prussian War, for example, his 1870 published address at the University of Berlin, *Über den Deutschen Krieg* (*The German War*), was widely cited and discussed.

Ducasse, Curt John (1881-1969)

Ducasse was a highly systematic philosopher and scarcely any field or topic escaped his attention. He criticized Hume's account of causality, advocated 'soft determinism' and developed an 'adverbial' realist account of our knowledge of the external world. He was a dualist on the mind-body relation, a 'progressive hedonist' in ethics, a defender of the 'will to believe', an expressionist in the philosophy of art, a scourge of art critics and a critic of theism. He also wrote on propositions, truth, signs, liberal education, linguistic metaphilosophy and paranormal phenomena. His influence on younger philosophers has been greatest, however, in the areas of causality, adverbial realism, progressive hedonism, the will to believe and aesthetics. Ducasse died in 1969, but his work remains significant, especially through his influence on Roderick Chisholm and Wilfred Sellars.

1 Life

Born in Angoulême, France, in 1881, Ducasse was educated at the Bordeaux Lycée, Abbotsholme School in England and, after emigrating to the USA, at the University of Washington and Harvard University. He received the Ph.D. from Harvard in 1912, having done his dissertation under the direction of Josiah Royce. He taught at University of Washington from 1912 to 1926, then at Brown University until 1958, when he retired. Ducasse helped establish the *Journal of Symbolic Logic*, and was the first president of the Association for Symbolic Logic. He was one of the clearest philosophical writers in the United States and always sought to avoid obscurity.

2 Causality and necessity

Ducasse was a perceptive critic of Hume's analysis of causality, according to which, objectively considered, 'cause' means only regularity among contiguous sequences of logically independent impressions: having observed without exception that one object follows another object, we thereby acquire a habit of mind, namely, the ' propensity, which custom produces to pass from an object to the idea of its usual attendant' (Hume 1739-40: 165). Ducasse was unimpressed with Hume's view. Two of his many criticisms are particularly effective. First, Hume's phenomenalism deprives him of the right to use the distinction between 'perceptions' and 'objects', without which his own rendition of the causal relation could not even be stated. Second, Hume's own position undermines his use of the concept of propensity. In Hume's world there can be only perceptions (impressions) which *are* but cannot *act*, while a propensity refers to what a thing or substance is capable of doing or is likely to do. Hence perception is too narrow a concept to sustain the ideas of propensity (see Hume, D. §2).

As an alternative Ducasse referred to the method of single difference: the strict experiment. He defined causation as the observable relation that holds between the three terms of a strict experiment - the complete state of affairs (S) wherein occur two and *only two* changes in a given time-period, one of which occurs immediately after and adjacent to the other, the second qualifying as proximate effect (E) of the first, the proximate cause. Both Hume and Ducasse, it would seem, confused the reasons we have for saying that x and y are causally related with the meaning of the term 'cause'. Hume saw the method of agreement as the primary way causal propositions are confirmed and so interpreted the meaning of 'cause' as 'constant conjunction'. On the other hand, Ducasse saw the method of single difference as the most reliable way causal propositions are known to be true and hence interpreted the meaning of 'cause' as 'the only change in S immediately prior to E'. It is clear that both methods under different conditions provide good reasons for saying that x is the cause of y, but if so they cannot also be given as definitions of the concept 'cause'.

For Ducasse, there are other necessities besides logical ones - the blow of a hammer physically necessitates breaking the glass, the death of John's wife psychologically necessitates his depression, and so on. His inclusive concept of necessity he labelled 'etiological necessity'. Though usually clear, Ducasse wrote ambiguously about this concept, sometimes portraying it as an ontological ingredient of the world and at other times denying it. On one hand, he wrote that when King Charles lost his head the swing of the axe *forced* his head to be severed from his body; that people directly perceive a bird perching on a branch to *cause* the branch to bend; and so on. Moreover he often referred to the distinction between agents and patients among the particulars of the worlds. On the other hand, he wrote that any 'power' analysis of causality would introduce a mysterious, ineffable element into causality and thus must be rejected. Ducasse had apparently caught something of the Humean virus when he least expected it. He certainly believed in the agent-patient view of causality, yet there was no possibility of

justifying this distinction unless he conceived some particulars to have the power to produce certain effects.

3 Adverbial realism

Ducasse's greatest contribution to philosophy is probably his 'adverbial' view of perceiving physical objects, a view developed by his student Roderick Chisholm and others (see Mental states, adverbial theory of §2). According to Ducasse, in everyday life, as we all agree, we directly perceive physical objects and some of their properties and we cannot avoid believing in their independent existence. Many philosophers, however, point out that we sometimes experience illusions and hallucinations and hence, at least in some cases, must be directly aware of our own sensations and impressions and are not apprehending physical objects. Further, since perception is the result of a long causal chain of physical and physiological stimulation which ends in the brain as a sensation, it would seem that we are *always* directly aware of our own sensations and impressions, and never of physical objects. Like Thomas Reid before him, Ducasse dismissed these arguments because they spawned an unsolvable dilemma: either the physical world becomes unknowable, or 'physical object' takes on a meaning radically different from what people ordinarily do in fact mean by the term.

It was to escape from this dilemma that Ducasse developed his adverbial view of sensation. He proposed that we reject sensations as entities and think of them instead as ways of sensing an object, expressed by adverbs, not nouns: 'I see bluely', not 'I see this blue colour'. Thus when a person sees something which looks blue, they are not directly aware of a blue sensation but are being appeared to bluely by an object. The adverbial view, Ducasse claimed, not only avoids the traditional dilemma; it also shows that it is impossible to state the sensationalist view without referring to physical objects as basic epistemic entities. How an object appears to people must make some reference to the physiological states of the observer and the physical conditions of observation; such reference to specific people and conditions is required *before* one can construct a substantive vocabulary of sensations. Ducasse also used the concept of variable appearings to counter the sensationalist argument from illusion and hallucination by accounting for them in terms of variability in the state of the observer and the physical conditions of observation.

4 Progressive hedonism

According to Ducasse various social contexts exemplify different moral codes, but none of the codes can itself be established as the right one and the others as wrong ones, because every code is equally tenable in its context, each being as logically arbitrary as the others. Ducasse called his view 'ethical liberalism' and, though it sounds like straightforward relativism, it is somewhat distinct from this traditional doctrine.

Since no ethical code can be proved to be the correct one, there is no way of establishing either egoism or altruism as the right attitude. Nevertheless there are other ways of changing attitudes than by argumentation; egoists may have their horizons broadened and come to empathize with other people. The point of a liberal education is precisely that of widening horizons by enlarging the range of ideas to be apprehended by students and by making them familiar with a wider range of people with whom they can learn to identify. According to Ducasse egoists have not been convinced by arguments in any shift from egoism to altruism; the point is that widening horizons and the knowledge of what it is possible to enjoy or care about have changed the egoist into a person who *in fact* cares about others. This view has come to be called Ducasse's 'progressive hedonism' (see Hedonism §1).

Progressive hedonism is a form of universal hedonism and hence, minus the relativism, is akin to utilitarianism (see Utilitarianism §5). Numerous criticisms have been made of utilitarianism, one of which is particularly relevant to Ducasse: a person may have to be dishonest in order to avoid starvation, but how is this situation compatible with progressive hedonism? Ducasse answered that, instead of saying that one should contribute to the general welfare, the progressive hedonist should recommend that one commit the smallest amount of evil commensurate with continued existence. Ducasse, then, became an early advocate of what has come to be called 'negative utilitarianism'.

5 The will to believe

What are the moral requirements in epistemology when there is insufficient evidence to decide an issue? Dickenson Miller (1942) argued that it is a moral duty to suspend judgment until further evidence becomes available. His friend Ducasse, however, believed that the only *moral* responsibility is to consult all available

evidence impartially; if the evidence is in balance, then one has the right, but not the duty, either to suspend judgment or to accept whatever alternative has life-sustaining value.

Ducasse insisted that this was the legitimate core of William James' article 'The Will to Believe' (1897), which Ducasse thought should have been called 'The Right to Believe'. Against Ducasse, Miller argued that believing without adequate evidence would relax one to the point of believing propositions for practical reasons when the evidence was sufficient to substantiate the denial of that belief. But Ducasse countered by pointing out an opposite spreading effect. He feared that Miller's 'sceptical' condemnation of belief where there is no preponderance of evidence might spread to areas where there is a supporting preponderance in the form of probabilities. Should we insist on near certainties and ignore acting on probabilities?

In later correspondence, however, Ducasse made the same mistake that James had made earlier and committed himself to the strong view that one *ought* to accept life-sustaining beliefs if the evidence is inconclusive - indeed, it is one's duty to do so. In Ducasse's words a 'fool's paradise' is preferable to a 'fool's hell'. He even suggested that in order to avoid the latter a person is justified in using psychological devises to strengthen commitment to the former. Miller was horrified at this suggestion, since such psychological conditioning, he claimed, would make it impossible to look for new evidence and evaluate it properly if encountered. Miller's criticism can be forcefully paraphrased thus: 'Is there a great difference between self-inflicted brainwashing and political brainwashing?'

6 Aesthetics

Ducasse formulated an expressionist theory of art according to which an artist's feelings or emotions, some quite subdued and nameless, are embodied in words, lines, colours, forms, sounds and motion. This self-expression of artists is objective in the sense that they create works of art which when contemplated yield back the feelings of which they are the attempted expression. This objectification of feelings must be consciously done and critically controlled to distinguish it from expressive activities such as sighing and yawning. The critical control usually involves much trial and error as artists experiment within their different media. The trial-and-error procedure helps to clarify and refine the feeling, and in this respect also gives to art creation an objective dimension. The feeling that a work of art expresses, then, is not identical with the original feeling of the artist but is a 'feeling image', a concept not clearly articulated by Ducasse but one which seems to be a recollection of a feeling rather than the feeling itself (see Artistic expression §5). There are many definitions of fine art which Ducasse flatly rejected, including Tolstoi's view that communication of feeling is an essential part of fine art (see Tolstoi, L.N.). For Ducasse it is no essential aspect of a work of art that consumers of it should have its feeling dimension communicated to them. Ducasse also separated art from the concept of beauty; for him art was wholly defined as objective self-expression. No doubt he established one sense of art which is independent of such traditional aesthetic concepts as beauty and communication; however, restricting the meaning of 'art' to objective self-expression seems as unnecessarily restrictive as it would be to limit the meaning of 'religion' to varieties of monotheism.

Outside academic circles Ducasse was well known for his criticism of art critics. They give biographical facts about artists, collate their pieces in chronological or stylistic orders and refer to previous artists who influenced them and those whom they subsequently influenced. Though this may be interesting discursive information, most of it does not help in forming artistic judgments. None the less Ducasse never denied that discursive scholarship can be an aid to appreciation and evaluation, if it serves as a guide for perceiving more acutely and for discriminating in greater detail. The proper role of the critic, Ducasse thought, is that of a guide in a foreign city who, on the basis of their thorough knowledge of the city, points out what onlookers might easily have missed on their own.

List of works

Ducasse, C.J. (1924) *Causation and the Types of Necessity*, Seattle, WA: University of Washington Press.(The most complete and thorough presentation of Ducasse's non-Humean analysis of causality. Unlike Hume's constant conjunction view, Ducasse argues that propositions are singular in nature.)

Ducasse, C.J. (1930) *The Philosophy of Art*, New York: The Dial Press.(Ducasse's classic statement of his expressionist view of art in which a work of art embodies some subtle nuance of feeling that can be captured by

a viewer as well as recaptured by the artist. This and his other popular writings on art led to his election to the presidency of the American Society of Aesthetics.)

Ducasse, C.J. (1944) *Art, the Critics and You*, New York: Oskar Piest.(A popular presentation of his aesthetic theory, but more importantly a stinging criticism of art critics who think that scholarly information about works of art is necessary for appreciation of art.)

Ducasse, C.J. (1951) *Nature, Mind, and Death*, The 1949 Carus Lectures, La Salle, IL: Open Court.(Ducasse's most elaborate and profound book, touching, as it does, on all the major areas of his interest from technical epistemology and metaphysics through a host of other issues culminating in a section on paranormal phenomena.)

Ducasse, C.J. (1968) *Truth, Knowledge and Causation*, London: Routledge & Kegan Paul.(A republication of the most important articles written by Ducasse in epistemology and metaphysics. It is a fruitful book for anyone who wants the technical philosophy of which Ducasse was such a master.)

Du Châtelet-Lomont, Gabrielle-Émilie (1706-49)

The name of this aristocratic woman, a true intellectual with a passion for mathematics, philosophy and science, is linked to that of Voltaire, whose life and interests she shared for fifteen years. In the rural retreat of Cirey they studied, disagreed, wrote and published. She was introduced to Newtonian science by Maupertuis and Voltaire but departed from their views, when she tried to combine Leibnizian metaphysics with Newton's empirically based science in her Institutions de physique (1740). She translated Newton's Principia from Latin into French and added a commentary on the system of the world (1745-9, published 1756).

Gabrielle-Émilie de Breteuil was born into an aristocratic family in Paris and showed an early interest in intellectual pursuits. As an adolescent she translated Virgil's *Aeneid* into French. Later she learned Italian and English. She developed a passion for astronomy and physics, and studied mathematics seriously in order to understand these sciences.

In 1725 she married Florent-Claude, Marquis du Châtelet and Comte de Lomont, by whom she had three children. The marquis, often away with his regiment, was tolerant of his wife's behaviour. She was able to combine an intellectual life with the worldly, social life of the aristocracy. Among her lovers were the Duc de Richelieu, the mathematician and early French Newtonian Pierre-Louis de Maupertuis, who taught her mathematics, and Voltaire, who, risking arrest after the publication of his *Lettres philosophiques* in 1734, took refuge at her family property at Cirey-sur-Blaise in Champagne. There they created a centre of learning and pleasure. They set up a well-equipped laboratory and performed experiments on light, fire, optics, and so forth. Among their visitors were the popularizer of Newton's optics, Francesco Algarotti, Maupertuis, Johann (II) Bernoulli and Samuel König, a Swiss mathematician and philosopher, who spent most of 1739 with the Cirey household and taught Madame du Châtelet mathematics and the metaphysics of Leibniz and Wolff.

At Cirey Voltaire composed his *Éléments de la philosophie de Newton* and *Traité de métaphysique* (published 1738 and 1784 respectively). When he submitted an essay on the nature of fire for the 1738 competition of the Academy of Sciences, her disagreement with his views led her to submit, without Voltaire's knowledge, her own entry. She especially criticized his material view of light and fire. For her, fire - which had no weight - justified Descartes's subtle matter, which Voltaire had consistently attacked. Although neither Voltaire nor Madame du Châtelet won, their entries were published by the Academy.

Madame du Châtelet's most lasting contribution to learning was her translation into French of Sir Isaac Newton's *Philosophiae Naturalis Principia Mathematica*, to which she devoted the last years of her life. It was published posthumously in 1756, seven years after her death. She also wrote an original work, her *Institutions de physique (Instruction in Physics)* (1740), a textbook written to introduce her son to science, in which she presented metaphysics as a necessary introduction to physics. She admitted her debt to Christian Wolff's *Ontologia* (1729) and to summaries by König of works by Wolff. The manuscript, in the Bibliothèque Nationale de France, shows she had prepared an earlier version before König's arrival which was not Leibnizian, except for the chapter on *vis viva* (kinetic energy). König converted her to the Leibniz-Wolff philosophy, for her the only satisfactory metaphysics. She rewrote the metaphysical chapters accordingly. Voltaire liked to believe she never was really convinced by this philosophy. However, she was very firm in her Leibnizian views. She had adopted the Leibnizian view of the force of moving objects and was reading Wolff's Latin works in 1738 before König's arrival (see Leibniz, G.W.; Wolff, C.).

Her disagreements with Voltaire led to a sort of public dialogue between them. She reviewed his *Éléments de la philosophie de Newton* in the *Journal des savants* (September 1738); he published an article on her *Dissertation sur la nature du feu* in the *Mercure de France* (June 1739) and a critical review of her *Institutions de physique* also in the *Mercure de France* (June 1741). Voltaire kept reaffirming his Newtonian views against her attacks. The Leibnizian principle of sufficient reason had caused her to abandon attraction at a distance, empty space and atoms, all part of Voltaire's Newtonianism.

While never denying that the world behaved according to Newtonian principles, she felt that science had to discover mechanical causes for all phenomena. She followed Leibniz and Wolff in adopting non-material monads,

which contained force, the sufficient reason for change in the material world. Force was conserved in a perfectly functioning universe. Voltaire remained very sceptical of metaphysics, and was particularly hostile to monads, since he was committed to attraction at a distance as the mysterious but divine force that kept the universe in operation.

Her stand on *vis viva* in the final chapter of her *Institutions* gave rise to a public dispute with Dortous de Mairan and indirectly with Voltaire. Was the force of moving bodies equal to the mass times the velocity squared, as Leibniz claimed, or to the mass times the simple velocity, the traditional view, supported aggressively by Mairan? Both Mme du Châtelet and Voltaire became involved in the dispute.

In her *Institutions* she attacked Mairan's view. Mairan, obviously piqued, about the time he became secretary of the Academy of Sciences (January 1741) replied in an open *Lettre à Madame la marquise Du Chastellet, sur la question des forces vives…*. She then published her *Réponse… à la lettre de M. de Mairan sur la question des forces vives* (1741), an attack both personal and insulting. Finally Voltaire submitted to the Academy his *Doutes sur la mesure des forces motrices* (1741), in support of Mairan, and attacking the Leibnizian view of his mistress, without mentioning her name.

Voltaire, like the periodicals of the period, admitted that Madame du Châtelet had given the French a clear, elegant account of the Leibniz-Wolff philosophy, which was little known in France.

Madame du Châtelet was also the author of a *Discours sur le bonheur*, written about 1747 and first published in 1779, and is considered the author of an unpublished manuscript of biblical criticism entitled *Examen de la Genèse*, in another area of interest she shared with Voltaire.

In 1748 Mme du Châtelet fell in love with the minor poet, Jean-François de Saint-Lambert, became pregnant by him at the age of 43 and died of childbed fever in Lunéville at the court of Lorraine.

Dühring, Eugen Karl (1833-1921)

Versatile and prolific, Eugen Dühring constructed a metaphysical system uniting naturalism with a priori principles, such as a 'law of definite number' which asserts that everything countable must be finite; hence, the natural world must be limited, and past time must have a beginning. Value judgments are based on natural drives and feelings: in particular, the concept of injustice arises from the resentment produced by injury. Since criminal law is 'a public administration of revenge', the deterrent function of punishment is irrelevant to its rightness. In politics, Dühring combined his socialism with a fervent racism, chauvinism and anti-Semitism.

Dühring was born in Berlin, the only child of a civil servant. He studied law, but when an eye complaint led to complete blindness, shifted to philosophy and political economy. Dühring gained his doctorate in 1861 and became *Privatdozent* at the University of Berlin in 1863, but his campaign against 'spiritual corruption' in universities and his attacks on professors led to his dismissal in 1877. Quarrelsome and litigious, Dühring continued to feud with editors and publishers, produced books on many topics, and championed Robert Mayer's claim for priority in establishing the conservation of energy. Having outlived his enemies, he died at Nowawes, near Potsdam, in 1921.

Dühring constructed a realistic and naturalistic system which he called *Wirklichkeitsphilosophie* ('philosophy of reality'), based on 'principles', which are not really universal propositions but indications of the conditions for gaining knowledge. The most important task for metaphysics, Dühring claims, is to eliminate false conceptions of infinity. The only meaningful concept of infinity is that of a succession which never reaches an end: a completed infinity is an absurdity or 'chimaera', even a self-contradiction. Dühring's finitism is expressed in what he terms 'the law of definite number'. Everything that can be counted must be finite in number. Since this mathematical axiom must apply to reality, the number of world-bodies at any given moment is a particular determinate number.

The most striking consequence of this principle is a denial of the eternity of the world. Because an infinite series of past events would be a completed infinity, there must be a first state of the world, a timeless stability or original chaos, though how this gave rise to a succession of change is a problem. Only for future time is infinitude meaningful, as it is no more than the absence of any final state. Similarly, space can be thought of as infinite only negatively, as the unlimited possibility of going further; and infinite divisibility cannot be imagined as a process leading to infinitesimal quantities.

Dühring's moral philosophy is a version of naturalism. Since thinking by itself can never produce an 'ought' out of an 'is', he argues, all ideas of right and wrong must be based on drives and feelings. In particular, our notion of injustice arises out of the natural impulse to retaliate against those who have harmed us. The reactive feeling of *ressentiment*, as Dühring terms it, which finds expression in the drive for revenge, is not produced by some moral judgment made on other grounds; on the contrary, it is what supplies the material content needed for any concept of justice. Civilized society has taken over the task of acting against offenders, rather than leaving it to individual vengeance; yet however universal and impersonal our conceptions of right and wrong may become, their underlying impulse remains the same. Criminal justice, even in its ideal form, is a public administration of revenge. Hence the death penalty is appropriate for murder, whether or not it discourages further crime: the employment of legal punishment for deterrence is a 'terroristic system', having nothing to do with justice (see Crime and punishment §§1-2).

More broadly, Dühring proposes an alternative to both pessimism and optimism by surveying the feelings and emotions that give value to life. Injustice is the greatest evil in the world, while the greatest good is harmonious interaction with others: here Dühring shows the influence of Ludwig Feuerbach in emphasizing human sympathy, love and mutual respect. He condemns asceticism for devaluing the natural side of human nature, and separating the spiritual from the sensuous. Satisfaction comes from striving for real goals, and trusting in the value of life; but religion is harmful, since it diverts attention from actuality to an imaginary world.

As a political economist, Dühring followed Henry Carey in suggesting a 'harmony' of labour and capital, and advocating measures to improve the worker's condition. His own 'socialitarian' programme envisaged future society as a network of egalitarian communes. However, Dühring opposed the International and its 'Jewish

ringleader' Karl Marx. A fervent racist, he called for the exclusion of Jews and the elimination of 'asiatism' in all its forms - including Christianity - from German culture, while rejecting Darwinism as a brutal, immoral and typically English doctrine.

Ironically, Dühring's most important influences were negative ones. Interest in his ideas among German socialists impelled Karl Marx and Friedrich Engels to construct a comprehensive philosophy of their own. Encouraged by Marx, Engels subjected Dühring's system to a detailed critique in *Herr Eugen Dühring's Revolution in Science* (1878), commonly known as *Anti-Dühring*, which became an official text for later Marxism. Engels rejects Dühring's apriorism in favour of an empiricist and inductivist approach and, perhaps provoked by Dühring's attack on the Hegelian aspects ofMarx's *Kapital*, defends the 'laws' of dialectic as general descriptions of natural processes, even affirming the presence of contradictions in reality (see Engels, F.).

Another contemporary to oppose Dühring was Friedrich Nietzsche. In Nietzsche's view, Dühring is right in tracing our familiar concepts of good and evil back to vengefulness, but wrong in overlooking other drives which are spontaneous and active rather than reactive, embody strength rather than weakness, and belong to conquerors and rulers rather than the oppressed. Nietzsche proposes to establish new values which express this 'will to power'; and when he condemns socialism as a politics of *ressentiment* it is, rightly or wrongly, Dühring that he has in mind.

Duhem, Pierre Maurice Marie (1861-1916)

Duhem was a French Catholic physicist, historian of science and philosopher of science. Champion of a programme of generalized thermodynamics as a unifying framework for physical science, he was a pioneer in the history of medieval and renaissance science, where he emphasized a continuity between medieval and early modern science. Duhem was also one of the most influential philosophers of science of his day, thanks to his opposition to mechanistic modes of explanation and his development of a holistic conception of scientific theories, according to which individual empirical propositions are not tested in isolation but only in conjunction with other theoretical claims and associated auxiliary hypotheses. Such a view of theory testing entails that there are no 'crucial experiments' deciding unambiguously for or against a given theory and that empirical evidence therefore underdetermines theory choice. Theory choice is thus partly a matter of convention. Duhem's conventionalism is similar in kind to that later advocated by Otto Neurath and by W.V. Quine.

1 Life

Born in Paris and educated at the École Normale Supérieure, Duhem took his doctorate (in mathematics) from the Sorbonne in 1888 with a thesis on the theory of magnetization by induction. He had made a first attempt at the doctorate (in physics) in 1884, while only a third-year student at the École Normale, with a thesis on the concept of the 'thermodynamic potential'. This concept was later to become the centrepiece of most of his work in physics. Although published two years later as Duhem's first book, the 1884 thesis was rejected mainly due to the opposition of Marcelin Berthelot, whose principle of maximum work - which wrongly asserts that chemical changes tend spontaneously to produce maximum heat - was criticized by Duhem. Undaunted by this rejection, Duhem took first place in the *concours d'agrégation*, the competitive examination for university teaching positions in France, in 1885. Two years later he began work as a lecturer in physics at Lille, where he met his wife, Marie-Adèle Chayet, whom he married in late October 1890 in Paris. A daughter, Hélenè, was born in September 1891, but the great tragedy of Duhem's life occurred in July 1892, when Marie-Adèle died after giving birth prematurely to a second daughter. Duhem never remarried, keeping household in later years with his devoted daughter and future biographer, Hélenè, who also arranged for the posthumous publication of the last five volumes of Duhem's ten-volume historical magnum opus, *Le système du monde*.

Duhem's conservative, Catholic orientation, his stubborn and contentious manner and the continuing opposition of politically influential, anti-clerical, senior French scientists like Berthelot all combined to prevent his ever winning an academic position in Paris. In 1893, he left Lille for Rennes, moving the following year to Bordeaux, where he remained until his death in 1916. Duhem deeply resented this lack of recognition. When asked whether he would be interested in a newly created chair in the history of science at the Collége de France in 1893, he replied that he would go to Paris as a physicist or not at all, but he was pleased when, in 1913, he was finally elected a non-resident member of the Académie des Sciences.

Few thinkers can match Duhem's breadth and versatility, for he made contributions of fundamental importance in three different areas - thermodynamics and physics, philosophy of science and history of science. His work in these areas divided roughly into three overlapping phases. First, from the mid-1880s to 1900, thermodynamics and physics were his dominant interest, but with treatises on elasticity and energetics still being published as late as 1906 and 1911, respectively. In 1892, Duhem began publishing a series of essays on questions of methodology that would culminate in the publication in book form of his most influential work in the philosophy of science, *La théorie physique. Son objet et sa structure* in 1906. It was also in the mid-1890s that Duhem published his first essays in the history of science, starting on the path that would lead him to such important historical works as his *Études sur Léonard de Vinci* (1906-13) and *Le système du monde* (1913-59).

A curious denouement to Duhem's prodigious literary outpouring was his publication a few months after the outbreak of the First World War, and shortly before his death, of a series of lectures under the title *La science allemande*. He regarded this work as his patriotic contribution to the French war effort. Drawing upon Pascal's distinction between *l'esprit géométrique* and *l'esprit d'finesse* (see Pascal, B. §5), Duhem excoriated what he characterized as the axiomatizing, deductive excess of the German scientific intellect, contrasting this with the healthy good sense (*bon sens*) displayed by the French mind in its choice of first principles. This good sense is

alleged to provide French thinkers with an anchor in intuitively apprehended truth not to be found in German science. However much one might lament this dubious excursion into national scientific typology, *La science allemande* can and should also be read as an intellectual autobiography, as Duhem's mature statement about his own preferred way of doing science.

2 Physics

Duhem's most important contributions to physics were in the areas of thermodynamics and physical chemistry (see Thermodynamics; Chemistry, philosophical aspects of §3). Indeed his entire scientific programme was driven by the conviction that a generalized thermodynamics would be the proper unifying scheme for physical theory, with all of chemistry and physics, including mechanics, electricity and magnetism, being derivable from thermodynamic first principles. The intellectual style evinced in this project could be characterized as a balanced combination of the abstract, axiomatizing geometric spirit and a *bon sens* not too rigidly controlled by empirical constraints in the choice of axioms, along with a total unconcern for mechanical models and a thoroughgoing scepticism about any underlying atomistic ontology.

Strongly influenced by the work of J.W. Gibbs and H. von Helmholtz, Duhem started from the concept of the 'thermodynamic potential', related to the Gibbs and Helmholtz free energies, which he deployed in a manner formally analogous to potentials in mechanics for the purpose of representing all physical and chemical changes. The programme, which finds its mature statement in Duhem's *Traité d'énergétique* of 1911, was not ultimately successful, but along the way Duhem made a number of enduring contributions to thermodynamics and physical chemistry. Among these were the Duhem-Margules and Gibbs-Duhem equations, the first clear definition of a reversible process in thermodynamics as a quasi-static limiting process, and the first general proof of the Gibbs phase rule. That these results were obtained in the context of a programme of generalized thermodynamics was sufficient to earn Duhem's work a warm reception among late-nineteenth-century German energeticists, such as Wilhelm Ostwald and Georg Helm. Duhem was also one of the first continental scientists to appreciate the work of Gibbs, penning the earliest critical examination of Gibbs' 'On the Equilibrium of Heterogenous Substances' (1876, 1878) in 1887 and promoting the French translation of Gibbs' works with his pamphlet, *Josiah Willard Gibbs, à propos de la publication de ses mémoires scientifiques* (1907).

3 History of science

In the mid-1890s Duhem began publishing some shorter papers on the history of mechanics and thermodynamics in the *Revue des deux mondes* and the *Revue des questions scientifiques*. In 1902 he published two major historical studies, *Le mixte et la combinaison chimique. Essai sur l'évolution d'une idée* and *Les théories électriques de J. Clerk Maxwell. Étude historique et critique*, the first of a series of such works that was also to include *L'évolution de la mécanique* (1903a), *Les origines de la statique. Les sources des théories physiques* (1905-6), *Études sur Léonard de Vinci, ceux qu'il a lus et ceux qui l'ont lu* (1906-13), and his greatest historical work, the ten-volume *Le système du monde. Histoire des doctrines cosmologiques de Platon à Copernic* (1913-59).

It was in the history of medieval and Renaissance science that Duhem made his most important contribution. Here his name is associated with the thesis that most of the important innovations of early modern science had roots in the medieval period sufficient to warrant our viewing the science of that later period as a continuous outgrowth of the earlier one and not as a radical, revolutionary break with a scholastic dark age, as had standardly been assumed by previous historians of science, such as William Whewell.

As late as the time of his 1903 *L'évolution de la mécanique*, Duhem still subscribed to the dominant view of the Middle Ages as a fallow period in the history of science between the Greeks and the revival of science in the late Renaissance. It was in the course of his work on his *Origines de la statique* (1905-6) that he first came to suspect otherwise, when his tracking down a few references to the then all but unknown Jordanus de Nemore led to his discovery of a rich medieval tradition, centred at the University of Paris, that was known to and influenced later authors. Most importantly, in his *Études sur Léonard de Vinci* (1906-13) and *Le système du monde* (1913-59), Duhem began to reconstruct the neglected science of the Middle Ages, including the work of such figures as Jean Buridan, Albert of Saxony, and Nicole Oresme, attempting to document the manner in which the pivotal contributions of Leonardo, in particular, drew upon these earlier thinkers.

A theological motivation was never far from the surface in Duhem's historical writings. In addition to seeking to undercut the popular anti-clerical modernism of the Third Republic by disputing claims to revolutionary novelty on behalf of modern science, Duhem also sought to reveal the role in intellectual history of divine providence in the form of what he termed an 'ideè directrice' leading science forward to a 'natural classification' as the endpoint of inquiry.

4 Philosophy of science

Duhem's philosophy of science is a species of conventionalism (see Conventionalism). It was first developed in a series of essays appearing in the early to mid-1890s in the *Revue des questions scientifiques*, but is best known from the presentation in Duhem's *La théorie physique. Son objet et sa structure*. This first appeared in 1904 and 1905 as a series of articles in the *Revue de philosophie*, and then in book form in 1906. The essential content of Duhem's position is also to be found adumbrated in his *ΣΩΖΕΙΝ ΤΑ ΦΑΙΝΟΜΕΝΑ, Essai sur la notion de théorie physique, de Platon á Galilée* (1908).

According to Duhem: 'A physical theory is not an explanation. It is a system of mathematical propositions, deduced from a small number of principles, which aim to represent as simply, as completely, and as accurately as possible a set of experimental laws'. Moreover, from a purely logical point of view, there will always be a multiplicity of different physical theories equally capable of representing a given set of experimental laws. The argument for this conclusion starts from the doctrine of epistemological holism, according to which a scientific hypothesis is tested not in isolation, but only as part of an entire body of scientific theory (see Theories, scientific). Duhem exemplified this through his critique of the Newtonian idea of the *experimentum crucis*, an experiment the outcome of which would, by itself, determine unambiguously the truth or falsity of a given scientific hypothesis. There can be no crucial experiment, according to Duhem, because in order to derive a testable prediction from a hypothesis we must draw upon a set of auxiliary assumptions concerning such matters as the functioning of the experimental apparatus and the absence of extraneous physical influences (see Crucial experiments). It follows that a negative experimental result could be explained by rejecting either the hypothesis in question or one or more of the auxiliary assumptions. Hence there will always be a multiplicity of empirically-equivalent total theories for representing any set of experimental laws, meaning that theory choice is underdetermined by empirical evidence, and that the community's choice of one among these alternative theoretical representations will have the status of a convention (see Underdetermination §3).

Nevertheless, there is progress in science, the history of a field like optics or mechanics revealing continuous convergence towards what Duhem terms a 'natural classification'. An analysis of scientific method proves that science does not provide explanations; it is an 'act of faith' that convinces us that such an order in our theoretical representations corresponds to the real order in nature. Duhem quotes his favourite philosopher, Pascal: 'We have an impotence to prove, which cannot be conquered by any dogmatism; we have an idea of truth which cannot be conquered by any Pyrrhonian scepticism'.

Here lies the explanation for the generally anti-metaphysical tendency of Duhem's thinking about scientific method. Thus, he criticizes what he alleges to be a typically English penchant for seeking mechanical models of physical phemonena, as illustrated by Maxwell's search for mechanical models of the electromagnetic ether, arguing that the search for models is as often as not an impediment to the progress of scientific inquiry (see Electrodynamics; Models §3). By contrast, he commends what he regards as the typically French geometric or axiomatic/formal approach to science, as exemplified in his own work in thermodynamics and other areas.

Duhem's avowed purpose in denying to empirical science the capacity to determine unambiguously the deepest truth about nature was thereby to reserve a place for theology as the arbiter of truth in metaphysics. This emerges with special clarity from his 1905 essay, 'Physique de Croyant', which he added as an appendix to the second edition of *La théorie physique*. But whatever Duhem's conservative, Thomistic, theological aims might have been, it was the anti-metaphysical bent of his philosophy of science that was prized by many of his postivistically inclined scientific and philosophical contemporaries, from Édouard Le Roy, who characterized Duhem's philosophy as an instance of the 'new positivism', to Ernst Mach, who was so taken by *La théorie physique* that he promoted its translation into German in 1908.

Duhem's philosophy of science differs in crucial respects from the conventionalism of H.J. Poincaré. Most

importantly, Duhem did not follow Poincaré in characterizing conventions in science as merely 'apparent hypotheses' that are, in fact, 'disguised definitions', to be distinguished from genuine empirically verifiable hypotheses. Duhem's holism entails that all of the propositions constituting a body of scientific theory are on an epistemic par, any possible differences in susceptibility to revision in the face of new evidence being a matter, not of principle - as in the difference between analytic definitions and synthetic empirical propositions - but rather a contingent, practical matter of the community's historically and sociologically conditioned degree of commitment to different pieces of the total body of scientific theory. This difference between the conventionalism of Poincaré and that of Duhem is reflected in the different varieties of conventionalism that grew up in later twentieth-century philosophy of science. Moritz Schlick and Hans Reichenbach adopted an essentially Poincaréan conception of the conventionality of coordinating definitions, while Otto Neurath, Albert Einstein and W.V. Quine adopted Duhem's holism, the latter two thinkers extending holism about the empirical content of theories to a holism about the meanings of individual terms in science.

Dummett, Michael Anthony Eardley (1925-)

For Michael Dummett, the core of philosophy lies in the theory of meaning. His exploration of meaning begins with the model proposed by Gottlob Frege, of whose work Dummett is a prime expositor. A central feature of that model is that the sense (content) of a sentence is given by a condition for its truth, displayed as deriving from its constituent structure. If sense so explicated is to explain linguistic practice, knowledge of these truth-conditions must be attributed to language users by identifying features of use in which it is manifested. Analysis of truth suggests we seek such manifestation in patterns of assertion. But scrutiny of those patterns shows that there is no distinction between use which manifests knowledge of classical truth-conditions, and use which manifests knowledge of a weaker kind of truth - for example, one which holds whenever we possess a potential warrant for a statement.

Such considerations motivate reconstruing sense as given by conditions for this weaker kind of truth. But rejigging Fregean semantics in line with such a conception is highly nontrivial. Mathematical intuitionism, properly construed, gives us models for doing so with mathematical language; Dummett's programme is to extend such work to everyday discourses. Since he further argues that realism consists in defending the classical semantics for a discourse, this programme amounts to probing the viability of antirealism about such things as the material world, other minds and past events.

1 Sense

Michael Dummett, English logician and philosopher of language, was educated at Oxford, where he spent almost all his academic career, and occupied the Wykeham Chair of Logic from 1979 to 1992. His numerous papers in books and journals began appearing in the early 1950s; major longer works stretch from *Frege: Philosophy of Language* (1973) to *The Origins of Analytical Philosophy* (1993a).

While at odds with most Oxford philosophers of his own generation and of its predecessor in the importance he attaches to formal techniques, Dummett preserves a fundamental Oxford perspective by insisting on the centrality of the theory of meaning. Pure philosophy, as an a priori discipline, he argues, can do no more than clarify thought. But we cannot take our access to thoughts as unproblematic. (Ignoring this is the error of 'code' conceptions of language, which in Dummett's view include that of H.P. Grice (§§2-3); for these take such access for granted, and then try to explain meaning by correlating utterances with thoughts as thus (mis)conceived.) For we need to explain the compositional nature of thoughts, and so to display them as structures of thought-elements (concepts). There is, however, no mental process consisting of the bare apprehension of a concept. Rather, thought for us requires a vehicle; and our only access to the structure of thought is through the structure of some such vehicle. Further, though images and so on may serve as vehicles for simple thoughts, language is the paradigmatic thought-vehicle, and essential for sophisticated thought. So a theory of thoughts is best based on a theory of a language apt to express them.

Dummett derives his guiding conception of such a theory of language from Frege, in a profound interpretation of the work of that philosopher, to the elaboration and defence of which many of his publications are devoted. This paradigm puts a theory of sense at the core of the theory of meaning for a language, charged with articulating how sentences express thoughts; it supplements this with a theory of force, which spells out the conventions enabling utterances to be classified as assertions, orders, questions and so on. The dichotomy, Dummett argues, is an essential one; the later Wittgenstein repudiated it at the cost of neglecting the systematicity of language (see Wittgenstein, L.J.J. §9).

The core theory of sense is founded on a syntax and a semantic theory. The former reads into each sentence of the language a structure out of finitely-many primitive syntactic elements. Then, relative to a given domain of objects, the semantic theory specifies, for each kind of primitive expression the syntax discerns, a sort of entity apt to count as the semantic value of expressions of that kind. Finally, rules of the theory explain how complex expressions, and in particular sentences, systematically assume semantic values in a way determined by their syntactic structure and the semantic values of their syntactic parts. Frege provided the detail of a model syntax apt for a wide range of languages, and of a semantic theory suited to such a syntax. Crucially, his account takes the semantic value of a singular term to be a specific object from the domain (its referent), and that of a sentence to be a truth-value,

classically conceived.

Given a semantic theory, an ‘interpretation’ for a language consists of a domain along with an assignment of semantic values to primitive expressions. With some sentence value(s) distinguished as ‘designated’, these interpretations fix a logic: *C* follows from premises *X* if and only if on any interpretation in which all members of *X* take a designated value, so does *C*. Specifying an interpretation, and so presenting the semantic values of primitive expressions in a specific way, gives them a sense; ‘the’ sense of the primitives of a functioning language is given by a specification sensitive to the antecedent meanings. Senses for complex expressions are then given by the specifications of their derivative semantic values which the semantic theory generates on the basis of their constituent structure; in particular, on the Fregean model at least, the sense of a sentence is given by that condition for its truth which is derived on the basis of its constituent structure.

How does sense, thus explicated, relate to linguistic ability? Dummett argues that the latter is not merely practical, like the ability to swim, but that it involves a substantial theoretical component, which the theory of sense spells out. Thus speakers are to be credited with knowledge of the truth-conditions of sentences as deriving from constituent structure, and it is in such knowledge that their grasp of the sense of a sentence consists. Attribution of such knowledge is unproblematic where the speaker can supply a non-circular verbal explanation of the truth-condition of a sentence, so that the knowledge concerned can be regarded as explicit and actual. But, on pain of circularity, not all cases can be like this. For the rest, we must reckon the knowledge involved either actual but implicit, that is, unconscious; or else explicit but hypothetical (so that our theory articulates only what *would* suffice to account for linguistic capacity, were it known explicitly, saying nothing of the mechanisms which actually underpin the capacity it characterizes). Either way, the theory of sense must justify such attributions, by showing how they meet but do not exceed what is required to account for features of the linguistic practice they purport to explain. Indeed, by pointing to the way the knowledge it attributes is manifested in use, it explains in what this knowledge consists (see Sense and reference §§1-3).

2 Truth, use and inference

Scrutiny of the relationship between key notions in the theories of force and of sense, Dummett thinks, reveals the point of contact between the speaker’s knowledge of sense and linguistic practice. For the archetype of the sort of force which an utterance may carry is the basic one of assertion, so a major task for the theory of force will be to articulate the conventions governing that practice, and in particular to delineate the conditions under which an assertion is correct, that is, unimpeachable *qua* assertion (even if still liable to more general criticism, for example, *qua* obscenity). In doing so, it links assertion with truth: for an assertion is correct if and only if made by a speaker possessed of what is conventionally counted an adequate warrant for its truth. This connection, suitably communalized, might almost serve to characterize the most primitive notion of truth: truth at its most primitive is the property a sentence has if and only if among us we possess a warrant which would render an assertion of it correct.

Almost; for in fact the condition for truth even at its most minimal must extend beyond our actual possession of a warrant. This follows from the logical behaviour sentences exhibit when embedded in more complex contexts, such as the antecedent of a conditional: ‘if some even number exceeding 2 is not the sum of two primes, Goldbach was in error’ says that Goldbach was in error under a condition including, but more generous than, that in which we possess a warrant for the antecedent because we can actually produce an instance of an even number of the relevant sort. Again, truth is what deductive reasoning preserves; and we can learn something new by drawing a deductive inference. But that would be impossible if reaching a true conclusion always meant reaching one for which we already possessed a warrant.

Classical truth is the concept obtained by widening the core notion of actual warranted assertibility until a statement is counted true if and only if a warrant for it could be obtained by a being able to transcend the limitations which restrict our observations to the local and the gross, and our surveys to finite domains. While Dummett sometimes reserves the word ‘true’ for classical truth, he also makes it clear that less radical widenings may produce concepts deservedly called truth-concepts. The one he discusses most is verificationist truth, which retains the human measure of warrants, but counts a statement true when our warrant for it is merely potential, not actual. Another is pragmatist truth, under which a statement is reckoned true if we potentially possess a warrant for everything following from the statement as a consequence. Evidently, a logic based on either of these alternative

truth-concepts would differ from the classical one, in ways it remains for theory to detail, though some points of difference are obvious immediately. In particular, the existence of undecidable statements - statements for which we possess neither a potential warrant, nor a guarantee that we will never possess one, such as statements about the remote past or future, or ones involving counterfactual conditionals or quantification over infinite domains - means that neither will follow the classical conception in validating the Bivalence Principle (that every proposition is either true or false).

The primordial connection of truth-concepts with assertion suggests that we look to patterns of assertive practice for behavioural expression of a speaker's grasp of truth-conditions. If, moreover, the grasp of truth-conditions is to be constitutive of attaching sense, the pattern of assertive practice associated with grasp of the truth-condition of a given sentence must be so structured as not to include assertions already presupposing understanding of the sentence itself. Thus Dummett rejects meaning holism, and postulates instead the existence of a hierarchy of sentences, with understanding of a given sentence presupposing a prior grasp only of sentences occupying a lower place in the hierarchy.

Now let a 'canonical' warrant for a statement at the lowest level of this hierarchy be some cognitive state - paradigmatically an observational one - determined by the semantic structure of the statement, and certified by the theory of force as sufficient for its correct assertion; and let a canonical warrant for a higher-level statement be a set of lower-level statements jointly providing adequate grounds for the statement in question, by the lights of the deductive logic of the underlying semantic theory, or such looser standards as the theory of force approves. Then a speaker may manifest grasp of verificationist truth-conditions by a disposition to assert a lowest-level statement when possessed of a canonical warrant for it, and a higher-level one when disposed to assert lower-level sentences constituting one of its canonical warrants. Similarly, a grasp of the pragmatist truth-conditions of a statement is manifested by a disposition to assert such lower-level statements as are guaranteed to be canonically warranted if the given one is. (And to act in ways consonant with such warrants, we may add. But such action too is reflected in patterns of assertion, because acting warrants the assertion that one has acted.)

Critically, however, there is no additional assertive pattern which unambiguously certifies that a speaker's grasp is of a *classical* truth-condition, as distinct from one of these weaker substitutes. The sole plausible candidate is that it is manifested in the additional propensity to reason with the full strength of classical logic. This is, however, an unreliable indicator, since we allow our deductive practices to be shaped by our semantic theorizing - including, perhaps, an illegitimate attribution to ourselves of a grasp of classical truth-conditions.

The inability of a theory of sense based on classical truth to meet the manifestation requirement suggests founding the theory on an alternative truth-concept. The matter of choosing between the verificationist and pragmatist concepts for this role is less substantial than may appear, Dummett argues; for the aspects of linguistic practice which each emphasizes - justification of and commitment by assertion - are so intertwined that, to the extent our practice forms a whole which is harmonious (in a sense apt for formal characterization), the same ultimate end will be reached from either beginning. What is unclear is how to frame a semantic theory apt to underpin a theory of sense based on either concept. Construing the semantic value of a sentence as a truth-value works only in the classical case. We can still take the sense of a sentence to be given by a condition for nonclassical truth; but the elaborating theory must proceed indirectly, and assign to sentences semantic values not themselves truth-values, but in whose terms truth may be defined. One paradigm is provided by Heyting's semantics for mathematical sentences, which takes as the semantic value of a sentence an effective division of mathematical constructions into those which do, and those which do not, prove the sentence, and defines verificationist truth in terms of such values. The urgent task for the theory of meaning is to find analogous nonclassical semantics apt to found theories of sense for less rarified areas of discourse. In the absence of these, our most detailed account of language rests unsatisfactorily on a suspect attribution to its users of a shady concept.

3 Realism and antirealism

Whereas, in Dummett's view, further philosophical issues typically arise through applying insights of the core theory of meaning to the language of specialist disciplines, the metaphysical issue of realism is distinctive inasmuch as, properly diagnosed, it is directly concerned with themes in the theory of meaning, and hence a semantic issue (see Realism and antirealism §4).

The leading idea is that the essence of a realist thesis is not the independent existence of a range of entities, but the objectivity of the truth of a set of sentences. The earlier Dummett seeks to cash objectivity in terms of bivalence, but baulks at classifying all rejections of bivalence as rejections of realism, citing in illustration Strawson's doctrine that sentences containing vacuous singular terms lack truth-value (see Strawson, P.F. §2). Hence his earlier writings seek to distinguish deep and shallow rejections of bivalence, Strawson's typifying the shallow; and regard realism as compromised only when rejection goes deep. His later view is that even Strawson's rejection of bivalence does repudiate a realism, namely Meinong's unlovely realism concerning nonexistent objects (see Meinong, A. §3); but further, that rejecting *any* feature of the classical semantic theory, not just bivalence, marks a departure from realism. So Russell's alternative to Strawson's treatment of vacuous singular terms also involves antirealism, since his Theory of Descriptions treats (apparent) singular terms nonclassically in not giving their semantic values by an assignment of referents (see Descriptions §2). In so far as the analysis of the theory of meaning sketched in preceding sections militates against classical semantics, therefore, it constitutes a case for global antirealism, though an incomplete one pending details of a suitable antirealist alternative.

In Dummett's terms, reductionism involves repudiating realism only when the semantics of the reducing theory, or the details of the reduction, preclude reading classical semantics into sentences of the reduced theory; notably, when they determine that truth as applied to such sentences is not bivalent, or that the semantic value of a singular term is other than its referent. Central-state materialism thus involves no antirealism: sentences and singular terms of mental discourse assume respectively the determinate truth-values and referents of the neurophysiological expressions to which they are reduced. A common reductive pattern which *does* entail antirealism arises out of subjunctive conditionals. Let 'Were A the case, B would be' and 'Were A the case, B would not be' be called 'opposites'. Then there is no general guarantee that one of a pair of opposites must always hold. Yet often reduction proceeds by reducing a sentence to a subjunctive conditional, and its negation to the opposite; so bivalence for the reduced sentences is flouted and realism rejected, unless special circumstances can be pleaded. Behaviourism and phenomenalism both exemplify this pattern and, lacking grounds for special pleading, qualify as antirealisms, though the commitment to rejecting bivalence was not recognized by historical phenomenalists.

Sundering the link between antirealism and reductionism allows for non-reductionist antirealisms, an exemplar of which Dummett finds in mathematical intuitionism. True, many formulations of intuitionism link it with reductionist doctrines of mathematics as the study of solipsistic mental constructions. But these, Dummett argues, are best construed metaphorically; he construes intuitionism as advocating a semantics for mathematical language based upon verificationist truth, embodying suggestions for the detail of such a semantics, and a mine of ideas for its extension beyond mathematics. These intuitionist sympathies fall short of open espousal, though Dummett is committed to mathematical antirealism in some form - his careful examination of Frege's philosophy of mathematics concludes that paradox is inevitable when classical logic combines with 'indefinitely extensible concepts' such as that of number. Tensed discourse constitutes another area for which any antirealism must be non-reductionist. Rejection of bivalence for future-tensed statements is familiar enough; a further Dummettian theme is that the apparent fixity of the past is not the barrier it may seem to a similar rejection for past-tensed ones.

List of works

This list comprises only books on philosophical themes; these include anthologies, in which almost all of Dummett's philosophical essays are collected.

Dummett, M.A.E. (1973) *Frege: Philosophy of Language*, London: Duckworth; 2nd edn, 1981.(Detailed discussion of Frege's philosophy of language, and themes arising therefrom.)

Dummett, M.A.E. (1977) *Elements of Intuitionism*, Oxford: Clarendon Press.(Text on intuitionist logic and mathematics, with much philosophical motivation.)

Dummett, M.A.E. (1978) *Truth and Other Enigmas*, London: Duckworth.(Anthology containing almost all philosophical papers published before 1976. See especially Essay 1, on truth; Essay 14, on philosophical motivations of intuitionism; Essay 21, on antirealism about the past.)

Dummett, M.A.E. (1981) *The Interpretation of Frege's Philosophy*, London: Duckworth.(Further defence of the

interpretation of Frege put forward in Dummett 1973.)
Dummett, M.A.E. (1991a) *Frege and Other Philosophers*, Oxford: Clarendon Press.(Anthology of papers entirely or largely about Frege and not previously anthologized.)
Dummett, M.A.E. (1991b) *Frege: Philosophy of Mathematics*, London: Duckworth.(Detailed examination of Frege's philosophy of mathematics.)
Dummett, M.A.E. (1991c) *The Logical Basis of Metaphysics*, Cambridge, MA: Harvard University Press.(The most systematic statement of Dummett's own overall position. Not for beginners.)
Dummett, M.A.E. (1993a) *The Origins of Analytical Philosophy*, London: Duckworth.(Traces the origins of the analytical movement, emphasizing the contribution of Frege.)
Dummett, M.A.E. (1993b) *The Seas of Language*, Oxford: Clarendon Press.(Anthology of almost all papers on metaphysics and philosophy of language not previously anthologized. See especially Essay 2 on meaning; Essay 8, on truth; Essay 18, on mathematics; Essay 20, the best introduction to realism and antirealism; Essay 11, for more detail on the same theme.)

Duns Scotus, John (*c.*1266-1308)

Duns Scotus was one of the most important thinkers of the entire scholastic period. Of Scottish origin, he was a member of the Franciscan order and undertook theological studies first at Oxford and later at Paris. He left behind a considerable body of work, much of which unfortunately was still undergoing revision at the time of his death. Notable among his works are questions on Aristotle's Metaphysics*, at least three different commentaries on the Sentences of Peter Lombard (the required text for a degree in theology) and a lengthy set of university disputations, the quodlibetal questions. A notoriously difficult and highly original thinker, Scotus was referred to as 'the* subtle *doctor' because of his extremely nuanced and technical reasoning. On many important issues, Scotus developed his positions in critical reaction to the Parisian theologian Henry of Ghent, the most important thinker of the immediately preceding generation and a severe Augustinian critic of Aquinas.*

Scotus made important and influential contributions in metaphysics, epistemology and ethics. In metaphysics, he was the first scholastic to hold that the concepts of being and the other transcendentals were univocal, not only in application to substance and accidents but even to God and creatures. In this, Scotus broke with the unanimous view based on Aristotle that being could not be predicated of both substance and accident, much less of, except by analogy, God and creature. Scotus argued in general that univocity was required to underwrite any natural knowledge of God from creatures or of substance from accidents. Given univocity, he concluded that the primary object of the created intellect was being, rejecting Aquinas' Aristotelian *view that it was limited to the quiddity of the sense particular and Henry of Ghent's* Augustinian *view that it was God. That is, Scotus argues that even the finite intellect of the creature is by its very nature open to knowing all being.*

Scotus' proof of the existence of God is the most ambitious of the entire scholastic period. Prior efforts at demonstrating the existence of God showed little concern with connecting the eclectic body of inherited arguments. Scotus' proof stands apart as an attempt to integrate logically into a single demonstration the various lines of traditional argument, culminating in the existence of God as an actually infinite being. As a result, his demonstration is exceedingly complex, establishing within a sustained and protracted argument God as first efficient cause, as ultimate final cause and as most eminent being - the so-called triple primacy - the identity within a unique nature of these primacies, and finally the actual infinity of this primary nature. Only with this final result of infinity is Scotus prepared to claim he has fully demonstrated the existence of God. Notable features of the proof include Scotus' rejection of Aristotle's argument from Physics VIII (the favoured demonstration of Aquinas), the reduction of exemplar cause to a species of efficient cause, important clarifications about the causal relations at issue in arguments against infinite regress, an a priori proof constructed from the possibility of God similar to that proposed by Leibniz, and the rejection of the traditional argument that the infinity of God can be inferred from creation ex nihilo.

Scotus is a realist on the issue of universals and one of the main adversaries of Ockham's programme of nominalism. He endorsed Avicenna's theory of the common nature, according to which essences have an independence and priority to their existence as either universal in the mind or singular outside it. Intepreting Avicenna, Scotus argued that natures as common must have their own proper unity which is both real and less than the numerical unity of a singular; that is, natures are common prior to any act of the intellect and possess their own real, lesser unity. They are accordingly not of themselves singular, but require a principle of individuation. Rejecting the standard views that essences are individuated by either actual existence, quantity or matter, Scotus maintained that the principle of individuation is a further substantial difference added to the species. This 'individual difference' is the so-called haecceitas *or 'thisness', a term used seldom by Scotus himself. The common nature and individual difference were said by Scotus to be really identical in the individual, but 'formally distinct'. The 'formal distinction,' developed by Scotus chiefly in connection with the Trinity and the divine attributes, is an integral part of his realism and was as such attacked by Ockham. It admits within one and the same thing a distinction between realities, formalities or entities antecedent to any act of the intellect to provide an objective foundation for our concepts. These formalities are nonetheless really identical and inseparably united within the individual.*

In epistemology, Scotus is important for his demolition of Augustinian illumination, at least in the elaborate defence of it given by Henry of Ghent, and the distinction between intuitive and abstractive cognition. Scotus

rejected Henry's defence as leading to nothing but scepticism, and set about giving a complete account of certitude apart from illumination. He grounded certitude in the knowledge of self-evident propositions, induction and awareness of our own states. After Scotus, illumination never made a serious recovery. Scotus' other epistemological contribution was the allocation to the intellect of a direct, existential awareness of the intelligible object. This was called intuitive cognition, in contrast to abstractive knowledge, which seized the object independently of whether it was present to the intellect in actual existence or not. This distinction, credited to Scotus by his contemporaries, was invoked in nearly every subsequent scholastic discussion of certitude.

*While known primarily for his metaphysics, the importance and originality of Scotus' ethical theory has been increasingly appreciated. Scotus is a voluntarist, holding for example that not all of the natural law (the decalogue) is absolutely binding, that prudence and the moral virtues are not necessarily connected and that the will can act against a completely correct judgment of the intellect. It is Scotus' theory of will itself, however, that has attracted the most attention. He argues that the will is a power for opposites, not just in the sense that it can have opposite acts over time but in the deeper sense that, even when actually willing one thing, it retains a real, active power to will the opposite. In other words, he detaches the notion of freedom from those of time and variability, arguing that if a created will existed only for an instant its choice would still be free. In this, he has been heralded as breaking with ancient notions of modality that treated contingency principally in terms of change over time. Scotus argued that the will, as a capacity for opposites, was the only truly rational power, where the rational was opposed to purely natural agents whose action was determined. In this sense, the intellect, as a purely natural agent, was not a rational power. Finally, Scotus endowed the will with an innate inclination to the good in itself apart from any advantage it might bring to the agent. This inclination or affection for the just (*affectio iustitiae*, as it was termed by Anselm), enabled the will to escape the deterministic inclination of natures toward their own perfection and fulfilment.*

1 Career

Despite his importance and influence, little is known with certainty about the life and career of Duns Scotus. The commonly reported details of his family origins, early education and entry into the Franciscan order are now regarded as suspect owing to their origin in a partially fabricated eighteenth-century chronicle. More reliable is the date of his ordination to the priesthood in 1291, from which it is inferred that he must have been born about 1266. Scotus probably began his theological studies at Oxford about 1288, although it is debated whether he also studied at Paris prior to 1302. In any event, it is certain that he was present in Oxford in 1300 as a bachelor in theology, at which time he was participating in disputations and beginning to revise his lectures given there on the *Sentences* of Peter Lombard.

Scotus, however, never became master of theology at Oxford. At the recommendation of the English provincial, he was instead sent to Paris to lecture on the *Sentences* for a second time, which he began to do in the autumn of 1302. His Paris lectures were interrupted in June 1303 when King Philip the Fair required declarations of allegiance from religious houses at the university during his dispute with Pope Boniface VIII over taxation of church property. Scotus was among some eighty Franciscans from the Paris convent expelled from France by Philip for siding with the pope. During his exile from Paris Scotus is thought to have returned to Oxford, at which time he may have held his Oxford *Collations*. Scotus was back in Paris to resume his lectures on the *Sentences* by the autumn of 1304, when he was nominated by the Franciscan minister-general, Gonsalvus of Spain, as next in line for the Franciscan chair in theology. In his recommendation, Gonsalvus attested that Scotus' reputation had already 'spread everywhere'. Scotus is accordingly thought to have incepted as master by early 1305.

As regent in theology at Paris, Scotus disputed one set of quodlibetal questions and perhaps his Paris *Collations*. For reasons that are unclear, he was soon transferred from Paris to the Franciscan house of studies in Cologne, where a document dated February 1307 names him as a lector. Nothing is known of his activities at Cologne, where he appears to have remained until his early death, traditionally given as 8 November 1308. Remarkably, Scotus produced the bulk of his substantial writings in a period of barely ten years.

2 Works

As with the details of his career, Scotus' works suffered greatly in transmission. It is fair to say that no scholastic thinker of his stature has been so burdened by misattribution and textual confusion. While much progress has been

made in untangling Scotus' corpus, fundamental questions remain, particularly concerning chronology.

Scotus' works can be divided into philosophical and theological writings, with the latter generally regarded as later and more definitive. The philosophical writings consist first of all of questions on Porphyry and on the *Categories*, *Peri hermeneias* and *Sophistical Refutations* of Aristotle. These logical works are all presumed to be early products of his arts training, and they appear to have exercised little influence. Much more important are Scotus' lengthy questions on the *Metaphysics* (only books I-IX are authentic), also traditionally regarded as an early work dating from his arts career. The questions on the *Metaphysics* are notorious for their difficulty, arising in part from the hundreds of revisions, additions and intrusions made to the text. Their traditionally early dating has been somewhat tempered in light of research indicating that certain sections appear to have been later. Finally, a much shorter set of questions on Aristotle's *On the Soul* is attributed to Scotus, but its chronology is uncertain.

Scotus' reputation, however, rests on his longer and more developed theological writings, and principal among these are his commentaries on the *Sentences*. A major advance of textual research on Scotus has been to tease apart the various versions of his *Sentences* that had been conflated even by his earliest disciples. At least three commentaries are now recognized: the *Lectura*, which are his earliest lectures on the *Sentences* at Oxford; the *Ordinatio*, a greatly expanded revision of the *Lectura*; and the *Reportatio parisiensis*, which are students' reports of his Parisian lectures. Of capital importance for the interpretation of Scotus is the chronological relationship of the *Ordinatio* and *Reportatio parisiensis*, because the treatment of important issues in the Paris lectures differs markedly from that in the Oxford commentaries. A governing thesis of the critical edition of this work has been that the *Ordinatio* formed the latest and most definitive of Scotus' commentaries, incorporating both his early Oxford *Lectura* and his Paris lectures. A revised tendency, however, has been to see the first book of the *Ordinatio* as earlier than the *Reportatio parisiensis*. In other words, it is increasingly thought that Scotus must have begun work on the *Ordinatio* before he left Oxford for Paris in 1302. Resolution of this must await further study of the Paris reports, which remain unedited for the first book.

In addition to his commentaries on the *Sentences*, Scotus left two sets of theological disputations. The first, his *Quaestiones quodlibetales (Quodlibetal Questions)*, certainly date from his regency at Paris and should be regarded as the mature work of a master at the height of his career. A second set of university disputations, the *Collationes (Collations)* are also important but have been little studied. As with the *Sentences*, Scotus has *Collations* from both Oxford and Paris. Finally, Scotus wrote two treatises, the *De primo principio (On the First Principle)* and the *Theoremata*. The former is a lengthy and systematic deduction of the existence and nature of God according to axiomatic method. Nearly two-thirds of the *De primo principio*, however, comes directly from the *Ordinatio*, which suggests that Scotus may not have finished the treatise himself. The authenticity of the *Theoremata* has been contested owing to a section which argues, among other things, that natural reason cannot demonstrate the existence of God. The *Theoremata* is a work nonetheless attributed to Scotus both by manuscripts and by his contemporaries.

3 Sources and method

After nearly fifty years of publication and research, the critical edition of Scotus' works has resulted in two general findings important for the exegesis of his thought. The first is that Scotus' single, most important source by far was Henry of Ghent, the leading theologian at the University of Paris in the generation after Aquinas. On one major issue after another, Scotus begins with an extensive analysis and criticism of Henry's position only to develop his own view in reaction to it. At least for his Oxford commentaries, Scotus' real textbook was not Peter Lombard's *Sentences* but, in effect, Henry of Ghent's *Summa*. The relation of Scotus to Henry, however, is complex and does not simply consist in the former rejecting Henry's conclusions. Scotus' own position is often indebted to Henry's vocabulary, distinctions and general philosophical framework. Even when he does not have Henry's opinion under direct consideration, he will presume Henry's prior discussion of the matter. Accordingly, Henry should be properly viewed as the major intellectual influence on Scotus as much as his principal adversary.

A second finding is that Scotus revised his works heavily by way of additions, annotations and insertions, termed *extra*, or 'outside Scotus' original text'. This method is especially apparent in the first book of the *Ordinatio* and in the questions on the *Metaphysics*. Scotus' additions and insertions to his initial text can run to pages and typically record further objections and replies, often lodged by a contemporary, and note cross-references to related arguments elsewhere. Consequently, at these places Scotus' texts cannot be read as finished products but as work

in progress containing several chronological layers.

4 The place of Scotus in medieval philosophy

Scotus occupied a pivotal place in scholastic thought, closing the thirteenth century and opening the fourteenth intellectually as well as chronologically. First of all, Scotus' focus on Henry of Ghent, quite apart from its obvious exegetical importance, was otherwise significant for the period. By in effect making a contemporary work the object of his commentary on the *Sentences*, Scotus fundamentally changed the programme and form of scholastic literature itself. While this change was already underway in the previous generation, Scotus nonetheless marks a clear divide between the thirteenth-century project of incorporating Greek and Arabic sources, as exemplified by Albert the Great, Bonaventure and Aquinas, and the fourteenth-century focus on contemporary opinion evident in William of Ockham.

However, Scotus' greater contribution lies in his philosophical innovations, which not only became frequently discussed opinions - Scotus is one of the most cited authors in the fourteenth century - but defined the very issues and terms of analysis for the next century. Among the important concepts introduced by Scotus must be considered the following: in metaphysics, the univocity of the transcendental concepts, proofs for the existence of God and the principle of individuation; in epistemology, the distinction between intuitive and abstractive cognition; and in ethics, the will as a rational power for contraries and the interpretation of Anselm's distinction between affection for justice (*affectio iustitiae*) and affection for what is advantageous (*affectio commodi*).

5 Univocity of the transcendental concepts

One of Scotus' most striking metaphysical positions was that being and the other transcendentals could be conceived as univocally common to God and creatures, substance and accident. In this, he broke with the unanimous view of the thirteenth century that being could not be predicated univocally of substance and accident, much less of God and creatures. The common scholastic opinion, based directly on Aristotle, was that being was predicated of God and creatures neither univocally nor equivocally but according to analogy (see Being). Univocal predication was taken to violate God's transcendence over creatures and equivocity to render natural knowledge of God impossible. Rather, being was said to be predicated according to analogy, which meant that it was asserted of God in a primary sense and of creatures in a related but derived sense. Analogy was therefore construed as a middle way between the extremes of univocity and equivocity, balancing the competing demands of God's transcendence and knowability.

In general, Scotus' position was that some univocal concept of being common to God and creatures was presumed by the traditional conviction that knowledge of the divine nature or attributes was naturally attainable. Scotus singled out Henry of Ghent for sustained attack on this score as part of a comprehensive and critical appraisal of his entire theory of knowledge, which was in general Augustinian (see Augustinianism). In his treatment of analogy, Henry was much more emphatic and explicit than previous discussions had been in claiming that being, when conceived in its utmost generality, did not form a single, common notion (*ratio*), but only two exclusive and proper concepts, one applicable only to God and the other only to creatures. He repeatedly stressed that there could be no separate notion of being distinct from those proper to either God or creature, so that being could be conceived only as either finite or infinite, created or uncreated. To admit an absolute concept of being apart from these two would simply be an admission of one common to both. Scotus argued from several angles that Henry could not consistently maintain that being resolved only into two proper notions, having no conceptual element in common, and at the same time uphold the possibility of natural knowledge of God.

Of Scotus' several arguments for univocity - at one point he outlines ten - the one labelled 'from certain and doubtful concepts' was regarded by his contemporaries as the most compelling. This argument was aimed squarely at Henry's repeated insistence that there could be no concept of being apart from the analogous and proper notions of infinite and finite being applicable exclusively to God and creature (see Henry of Ghent). An intellect certain about one concept but doubtful about others, has a concept about which it is certain that is different from the concepts about which it is doubtful. We can be certain that God is a being, while doubting whether God is infinite or finite being. Therefore, the concept of being is different from, and hence univocal to, the concepts of infinite or finite being. Scotus takes the first premise to be evident, for a given intellect cannot be both certain and doubtful of the same concept. The second premise is true *de facto* because past thinkers, such as the Presocratics, disagreed as

to whether the first principle was finite or infinite. Yet, in attempting to establish one of these alternatives, no philosopher ever doubted that the first principle was a being. Being must therefore have a separate, distinct concept.

Put more generally, Scotus' point is that prior to demonstration, the intellect is doubtful whether God is an infinite or finite being. Yet, such a demonstration must be based upon something certain about God, for otherwise it would proceed from premises doubtful in all respects. Thus, unless the concept of being is admitted as certain, apart from the doubtful concepts of infinite and finite which are themselves the object of demonstration, no certain reasoning about God will be possible. Henry's refusal to admit a concept of being distinct from any proper to God therefore entails that the intellect is either certain and doubtful of the same notion or certain of none at all.

In a similar line of attack, Scotus is more explicit still that Henry's denial of a univocal concept of being renders natural knowledge of God impossible. A creature causes a concept that is either common to it and God or proper to God alone. Since Henry denies the former, he must hold the latter to explain the natural origin of our concepts of God. Scotus, however, argues that it is impossible for a creature to cause directly any concept wholly proper to God. In general, an object can only produce a concept of what it contains either as an essential part or an essential property, as is evident from the traditional division of essential predicates. Obviously, the creature can contain nothing proper to God as either a part or property of its essence without violating divine transcendence. Thus, if a creature can directly produce any concept applicable to God at all, it must be one that is common rather than proper.

Finally, Scotus applies these same criticisms to the very foundations of all scholastic accounts for natural knowledge of God, the Anselmian doctrine of pure perfections and the Pseudo-Dionysian procedure of removal and eminence. According to Scotus, both of these presuppose univocity, so that 'All the masters and theologians seem to use a concept common to God and creature, although they deny this verbally when they apply it' (*Lectura* 1 d.3 n.29). Anselm's doctrine holds that we attribute to God those perfections found in creatures which are pure in the sense that, conceived in themselves, they entail no imperfection, such as will, intellect or wisdom. These perfections are defined by Anselm generally as 'what absolutely is better to be than not' (see Anselm of Canterbury). But by this definition, something is first determined to constitute a pure perfection and then on that basis attributed to God, not the reverse. Pure perfections abstracted from creatures must therefore have some meaning that is prior to any they have as proper to God alone. Scotus makes the same point regarding the Pseudo-Dionysian methods of removal and eminence (see Pseudo-Dionysius). According to Scotus, all metaphysical inquiry about God proceeds by taking some formal notion (*ratio formalis*) and removing from it all imperfections with which it is found in a creature. For example, we take the formal notion of the will - the power for opposites - and remove any limitations connected with its existence in a creature, such as variability. We then attribute it to God by conceiving of it not just as lacking imperfection, but as possessing the greatest degree of perfection, such that it is omnipotent. This process presumes that the formal notion of the will stripped of creaturely limitations is the same notion of will assigned the highest degree of perfection; otherwise the first step of the procedure would simply have no relevance to the second. If nothing of the notion abstracted from creatures remains when we attribute it to God, then perfections in creatures have nothing to say about the perfection of God.

The outcome of the above arguments is Scotus' revision of the structure of the concept of transcendental being. In place of Henry's scheme, where being taken in its ultimate generality resolves into a pair of simple notions proper to God and proper to creatures, Scotus admits a single, simple concept which is common to both. As a result, the analogous concepts of being proper to God and proper to creatures, which for Henry were simple and irreducible, became for Scotus composite, comprising the common notion of being and the determining concepts of infinite and finite.

It is important to stress that in these arguments Scotus does not entirely set aside the received doctrine of analogy. He of course admitted that the concepts of being proper to God and proper to creature were analogous. His fundamental point is rather that unless there is some underlying concept of being common to these analogous ones, then they will in fact turn out not to be analogous at all but purely equivocal, thus rendering natural knowledge of God impossible. What Scotus did set aside was reliance on the analogous relationship itself as sufficient to account for any proper concept of God. Since knowledge of a relation is posterior, not prior, to any knowledge of the terms related, analogy does not explain but presupposes a knowledge of being as proper to God. Accordingly, some

univocal, conceptual community between God and creatures is demanded by the traditional project of natural knowledge of the divine nature or attributes.

6 Primary object of the intellect

Given univocity, it seems to follow directly that being is the primary object of the intellect, for the concept of being is common to, and hence more primitive than, any notion proper to either God or creatures. Scotus in fact draws this conclusion, arguing that unless the concept of being is univocal, there can be no object encompassing all that the intellect can know. Thus, in addition to ensuring the possibility of natural knowledge of God, the other important epistemological function of univocity is to provide the intellect with a primary or defining object.

To avoid what he saw as equivocation on the issue, Scotus distinguished three different viewpoints from which an object of the intellect could be considered primary: generation or origin, perfection and adequation. The first two were relatively uncontroversial, since there was broad agreement that all knowledge originated from the senses and that God constituted the highest knowable object. Accordingly, Scotus concluded that the specific nature of the sense particular was first in terms of the generation or origin of knowledge. In a similarly conventional position, Scotus put God as the first object in the order of perfection absolutely speaking, while the most perfect object proportioned to our intellect was the sensible nature. (Scotus, like most, refined these positions with various qualifications and distinctions.) The order of adequation, however, was more disputed, for here the primary object defined the nature of the intellectual power as such.

By ‘adequate’ Scotus meant what Aristotle called the ‘commensurately universal’, which formed one of the conditions of strict demonstration outlined in the *Posterior Analytics*. The adequate object of a power is that which is coextensive and commensurate with all objects over which that power ranges. It is in this sense that the primary object circumscribes the scope of a power and hence marks it off as distinct from other powers. In general, Scotus recognizes two ways in which an object may be adequate: either because it forms a universal nature or aspect (*ratio*) found in all things which a power surveys, such as colour in the case of sight, or because it is a single, most perfect object that includes within itself all the other objects governed by a power. In the case of the intellect, Scotus says that an object is adequate in the first way by community or predication, for it is common to and hence predicable of all that is intelligible; in the second way, an object is adequate virtually, for by understanding it, the intellect is moved to understand all else that is intelligible.

Scotus reports two competing opinions on the adequate object of the intellect, representing broadly Aristotelian and Augustinian theories of knowledge. The first is the well-known position of Aquinas, taken to represent the Aristotelian orientation, that the adequate object of the human intellect is the essence or quiddity of the sense particular. Scotus argues against Aquinas’ position on both theological and philosophical grounds, maintaining in each case that the adequate object concerns the nature of the power as such. Theologically, Scotus rejects Aquinas’ position because, in limiting the scope of the created intellect in its nature to the material quiddity, it rendered the knowledge of the immaterial essence of God promised in beatitude impossible. On the same grounds, Scotus rejects Aquinas’ explanation that, since ‘grace perfects nature’, the intellect will be elevated by a supernatural quality that will enable it to attain an immaterial object. While Scotus of course holds that a supernatural grace is required for our intellect to have direct vision of God, he denies that any supervening quality can modify a power so as to change its adequate object. In that case, the power is not simply perfected but, by definition, transformed into a power of an altogether different nature. Philosophically, Scotus argues that on Aquinas’ position the science of metaphysics would be impossible, for the intellect cannot acquire a science whose object exceeds the scope of the primary object of the intellect itself. But the object of metaphysics, being *qua* being, is more universal than material natures.

The second opinion, which represents an Augustinian approach, is that of Henry of Ghent, who posited God as the primary object of the intellect. As indicated above, Henry held that being and the other transcendentals taken in their utmost generality resolved into two distinct notions, one proper to God and the other to creatures. Henry had to designate one of the two as primary as regards our intellect, and he argued that those proper to God were prior. This followed from his strong commitment to an Augustinian theory of illumination, according to which the essence of a creature was truly known only by reference to its eternal archetype or idea in the mind of God (see Augustinianism). Scotus replies that, as indicated, if God is the adequate object of the created intellect, the divine nature must either be common to or virtually include all that is intelligible. The divine essence is obviously not

universally common to all intelligible objects, since God cannot be predicated of creatures. Although the divine essence does virtually include all that is intelligible, God is not on this account the adequate object of any created intellect. If this were the case, then the human intellect would be moved to understanding all intelligibles by a single object, namely the divine essence, rather than directly by those intelligibles themselves. The divine essence, of course, can function as an object in this way only for the divine intellect, which is to say that God is the adequate object of the divine mind alone. By way of a corollary to his refutation of Henry, Scotus also excludes on similar grounds substance as the adequate object of the intellect in the sense that it virtually contains accidents. This would mean that accidents could only be known through substance, which is false, since accidents themselves can move the intellect as intelligible objects.

Having excluded both God and substance in his refutation of Henry, Scotus concluded that no single object can be primary for the created intellect in the sense that it virtually contains all else that is intelligible. Therefore, if there is a primary, adequate object of the intellect, it must be such owing to its community. Since nothing is more common than being, it must be the primary object of the intellect. Scotus notes that this presupposes a univocal concept of being, so that if univocity is denied the intellect can have no adequate object.

In making being the primary object of the intellect, Scotus was in fact tacitly advancing yet a third opinion, that of Avicenna (see Ibn Sina). In central passages of his *Metaphysics*, Avicenna had made being both a primary conception of the mind and, in explicit contradistinction to either God or substance, the proper subject of a universal science of metaphysics. These texts strongly implied that Avicenna had seen being as the primary object of the intellect, prior to both God and creatures. Henry of Ghent had already explicitly raised just this interpretation of Avicenna in order to reject it forcefully on the grounds that it entailed a univocal concept of being. Henry's analysis was not lost on Scotus, who adopted the Avicennian position as a consequence of his doctrine of univocity.

7 Proofs for the existence of God

Duns Scotus' argument for the existence of God was perhaps the most ambitious of the scholastic period. Running to hundreds of pages and comprising dozens of interim conclusions and corollaries, it exists in at least four significantly modified versions, one in each of his three commentaries on the *Sentences* and separately as the treatise *De primo principio*. Among its distinctive features are the demonstration of the so-called 'triple primacy', the rejection of Aristotle's proof from motion, the definition of essentially ordered causes, the argument from possibility and the demonstration of God as infinite being.

According to Scotus, the highest naturally attainable concept of God is that of an actually infinite being. Consequently, Scotus holds that a complete argument for the existence of God can demonstrate nothing less than that some being is actually infinite. For Scotus a proof for a first efficient cause, such as Aquinas' second way, would not itself fully constitute a demonstration that God exists, but, as will be evident, would be merely a preliminary step in such a demonstration. Thus whereas most scholastics, like Aquinas, first establish that God exists and only later derive infinity as a divine attribute, Scotus requires the demonstration of infinity as logically necessary to establish God's existence itself. As a result, the structure of Scotus' proof is exceedingly complex, involving a good portion of his entire natural theology.

The overall structure of Scotus' demonstration comprises three large, principal steps divided into two main articles. The first step establishes that there is a first efficient and final cause and a most perfect being, the second that these three coincide in a unique nature, and the third that this nature is actually infinite. The first two steps together constitute the first article, which Scotus says establishes God according to the relative properties of causality and eminence (in other words, perfection), and the third step forms the second article, which reaches God according to the absolute property of actual infinity. The establishment in the first half of the proof of something primary according to each of the relative properties of efficiency, finality and eminence is referred to as the demonstration of the 'triple primacy.' All of these steps are intricately argued and supported by sometimes large preliminary results, such as that God has both an intellect and will as preparatory to the proof of actual infinity.

As in other areas of his thought, Scotus' proof reveals the influence of Henry of Ghent. Scotus took over the structure of the triple primacy directly from Henry's attempt to schematize the eclectic body of received arguments for the existence of God according to the Pseudo-Dionysian ways of causality and eminence (see

Pseudo-Dionysius). By subdividing causality into efficient, formal or exemplar, and final causes and interpreting eminence in terms of degrees of perfection, Henry sought to reconcile the disparate arguments from the Aristotelian (efficient and final cause) and Augustinian (exemplar cause and eminence) traditions. In an otherwise important metaphysical step, Scotus maintained against Henry that exemplar cause was simply a species of efficienct cause, and therefore eliminated it as a separate class of argument for the existence of God on the grounds of logical economy. He thereby streamlined Henry's original divisions of causality and eminence to the three of the triple primacy.

8 The proof from efficient causality

Each of Scotus' proofs for a primacy in efficient cause, final cause and eminence contains three main conclusions: that there is a first in that order, that it is uncaused and that it actually exists. Because Scotus establishes these three results principally for efficienct causation and then applies them to the other two cases, it will be sufficient to examine each of these three conclusions leading to a first efficient cause.

Before beginning the proof from efficienct causation proper, Scotus explains that he is demonstrating a first efficient cause of being and explicitly discards Aristotle's argument for a prime mover in *Physics* VIII. Scotus does so not because he thinks Aristotle's proof invalid but, again, on grounds of economy. To prove a first cause of motion is not necessarily to prove a first efficient cause of being. While the two may coincide in reality, further demonstration is required to establish this identity. Including Aristotle's physical proof would therefore necessitate a further step. Prior to Scotus, Aristotle's approach had been increasingly seen as inferior to Avicenna's strictly metaphysical proof based on necessity and possibility, especially by Henry of Ghent. Scotus, however, represents the final step where *Physics* VIII is omitted altogether from the standard corpus of arguments for God.

The first conclusion under efficienct causation, then, is that there is some efficient cause absolutely first, so that it neither exists nor exercises its causal power by virtue of some prior cause. Scotus' main argument for this first conclusion is brief. He formulates the initial premise broadly to include even possible effects: some being can be caused efficiently (*aliquod ens est effectibile*). It is therefore either caused by itself, by nothing or by another. Since it cannot be caused by nothing or by itself, it is caused by another. This other is either a first efficient cause in the way explained or it is a posterior agent, either because it can be an effect of, or can cause in virtue of, another efficient cause. Again, either this is first, or we argue as before, and some prior cause is required. Thus, there is either an infinity of efficient causes, so that each has some cause prior to it, or there is a first cause posterior to none. Since an infinity of causes is impossible, there must be a primary cause that is posterior to none.

This argument immediately encounters two objections, and Scotus' replies to them contain the bulk of his proof. The first is that the argument begs the question because it assumes that an infinite regress of causes is impossible. Here is it observed that the philosophers (that is, Aristotle and Avicenna) admitted an infinite series of causes, for they held that the generation of individuals could proceed to infinity, and hence every generating agent would have some prior cause. The second objection is that Scotus' argument is not strictly demonstrative because it is based on premises that are contingent, namely, that some effect exists. As such, the proposed proof lacks the necessity required of Aristotelian demonstration in the proper sense.

9 Essentially-ordered causes

In response to the first objection, Scotus defines the precise nature of causal relations at issue in arguments against infinite regress. According to Scotus, they do not concern simply essential as opposed to accidental causes, but rather essentially-ordered as opposed to accidentally-ordered causes. The former concern only the relationship that a single cause bears to its given effect, namely, that the effect arises from the nature of the cause rather than from something incidental to it. Essentially-ordered causes, however, concern the relationship of several causes to each other in jointly producing an effect. As defined by Scotus, there are three features of essentially-ordered as opposed to accidentally-ordered causes. The first is that the posterior cause depends upon the prior for the very exercise of its causality and not just for its being, which can be the case in accidentally-ordered causes. The second is that essentially-ordered causes always differ in nature so that the prior cause is more perfect in kind. This is a consequence of the first feature, for given two causes of the same nature, either is sufficient to produce the same effect. Finally, essentially-ordered causes must be simultaneously present to produce their effect, for otherwise from the second feature, some perfection in causality required for that effect would be missing.

Given this distinction, Scotus excludes the counterexample drawn from the philosophers, since it concerns an infinite series of temporally successive, generating causes. The causes in such a series are therefore not essentially but only accidentally ordered to each other in producing a given effect, for the posterior cause does not depend upon the prior for its causal action itself, but only for its existence. This is clear, for all the generating causes in the series are individual agents of the same nature or species, and thus not all are required simultaneously to produce the same effect. For instance, parents can produce a child whether or not their own parent or grandparent is alive. Rather, Scotus directs his argument against an infinite series of causes upon which the entire succession of individual agents itself would depend. Scotus claims that no philosopher admitted an infinite series of such essentially ordered or 'ascending' causes.

Having so defined the notion of causality operative in the proof, Scotus remains content to give five brief arguments against infinite regress, based in part upon the received reasoning of Aristotle's *Metaphysics* II and Avicenna. An exception is the fifth of these arguments, for here Scotus establishes the possibility of a first efficient cause, the actual existence of which he deduces later. Scotus argues that since efficient causality does not of itself imply imperfection, it is possible for it to exist in some nature without imperfection. That is, efficient causality, like wisdom or intellect, is a 'pure perfection'. However, if there is an infinite regress in efficient causes, then all would be dependent on some prior cause and efficiency could never be found without imperfection, contrary to assumption. Therefore, a first efficient cause in the sense defined must be possible. While seemingly weaker than the other arguments against infinite regress in that it establishes only the possibility of a first efficient cause, this result enables Scotus to construct a strict demonstration which he claims is necessary.

10 Proof from possibility

To the second objection, that the proof began from contingent premises and thus was not a true demonstration, Scotus replies that his argument for a first efficient cause can be formulated with either existential or modal premises. In the first way, the argument begins with the actual existence of some effect or change and argues directly to the existence of a cause owing to the correlative nature of effect and cause. Formulated in this fashion, the argument is based on contingent but evidently true premises. In the second way, the argument takes its premise from the possibility of some effect and concludes to the possibility of a cause. The actual existence of a first efficient cause is then deduced from its possibility. In this way, the argument can be recast so as to be a necessary demonstration, for the premises are statements not about the actual existence of some effect but about its nature or possibility. Scotus draws out the necessary argument from possibility in the last conclusion concerning efficient cause.

Having answered these two objections, Scotus proceeds to the remaining two of three conclusions necessary to establish a primacy in efficient causality. The second is that the first efficient cause is uncausable, with respect to both its own existence and its ability to cause. As Scotus indicates, this conclusion simply makes explicit the notion of 'first' already demonstrated in the arguments against infinite regress. The third and final conclusion is that an efficient cause first in this sense actually exists. As established in the fifth argument against infinite regress, a first efficient cause is possible. Scotus then argues that if such a cause is possible, it must actually exist. If it does not exist, then it could only be possible if some other cause was able to bring it into existence. But such a first efficient cause is absolutely uncausable, so that if it does not actually exist, it is impossible for it to exist. Therefore, if the first efficient cause can exist, it does exist. Alternatively, Scotus says, the same conclusion can be reached by the other traditional arguments recorded against infinite regress, although, as indicated in the above reply to the second objection, they begin from contingent premises.

11 Actual infinity of first efficient cause

After establishing the existence of a first efficient and final cause and most perfect being, and their identity in a unique nature, Scotus then moves to the actual infinity of that nature. As indicated, Scotus does not consider the existence of God to have been proven until actual infinity has been demonstrated. He derives the infinity of this primary nature from its properties of efficienct causality, final causality and eminence. The demonstrations based on efficient causality are notable.

Scotus considers two standard arguments for the infinity of the first efficient cause, both treated in some detail by Henry of Ghent in his question on divine infinity, and then constructs a third of his own. The first, based on

Aristotle's *Physics* VIII, is that since the first mover causes an infinite (that is, beginningless) motion, it must be infinite in power. Scotus, however, sees the argument as needing considerable expansion to establish infinity in the sense desired. First of all, to avoid basing the argument on the false assumption of an eternal world, he argues that the antecedent could be changed to the weaker claim that it is possible for God to cause an infinite motion. (Scotus, like Aquinas, regarded the eternity of the world as factually false but not impossible (see Eternity of the world, medieval views of).) Scotus claims that the consequent equally follows if God can, but in fact does not, produce an eternal motion. Second, he recognizes that a cause is not infinite in power simply because it produces an effect or succession of like effects - in this case the uniform rotations of the outermost heaven - for an infinite duration. Given a finite effect of infinite duration or an infinite succession of such effects, it only follows that their cause is also infinite in duration, not necessarily in power or perfection. Thus, Scotus revises Aristotle's original reasoning by arguing that the prime mover is causally responsible for the entire infinite succession of motions and derived effects taken together and in their totality. This he does in several ways, all of which depend upon recognizing that the prime mover, since it is the first efficient cause, depends on nothing else for its causal power. As such, the prime mover must possess within itself all at once the total power required to produce all of its effects realizable over an infinite time, for it can receive no power from any external cause. Since these effects are infinite in number, it must be infinite in power.

In addition to the Aristotelian approach based upon the prime mover as the first efficient cause of motion, Henry advanced a second argument for divine infinity based on God as the first efficient cause of being, that is, on God as creator. Henry argued that since the distance traversed from nothing to being in the act of creation *ex nihilo* was infinite (for a finite distance presupposes two finite beings), God had to be infinite in power. Whereas Scotus found the first approach based on Aristotle's *Physics* salvageable, he rejected outright this second argument based on creation. First of all, he noted that the argument requires that creation be taken in the revealed sense of a temporal beginning of the world, which is a matter of religious belief, rather than in the philosophically demonstrable sense of causal dependence. Secondly, Scotus denies that there is an infinite 'distance' between being and nothing. Contradictories are not distant in the sense that there is some interval between them, for they are immediate, but only in the sense that one extreme is more perfect than the other. Thus, two opposed extremes cannot be more 'distant' than the more perfect of the two. But the more perfect extreme in creation is merely finite. Thus, while a creature is infinitely distant from God, since the more perfect extreme is infinite, it is not so distant from nothing.

Scotus' third and preferred argument for infinity is drawn from exemplar causation, that is, from the efficient cause considered as an intellective agent. Prior to this proof, Scotus first establishes three necessary preliminary results: that the first cause has an intellect and will, that its intellectual and voluntary acts are identical to its essence and that it knows all that can be known both distinctly and actually. From this he argues that since the divine intellect knows distinctly and actually all that can be known, it knows these things all at once, for an intellect knows successively only if it moves from confused to distinct or from potential to actual knowledge. The things that can be known are infinitely many; therefore, since the intellect of the first efficient cause knows infinitely many things at once, it is actually infinite.

In sum, then, Scotus accepts proofs for infinity based upon the first efficient cause as prime mover and exemplar but not as creating cause. After completing further proofs for infinity based on finality and eminence, he concludes that the existence of God has been demonstrated according to the highest attainable concept (see God, arguments for the existence of).

12 Universals and individuation

Generally speaking, Scotus is regarded as a realist on the issue of universals because he admits that the universal has some reality and unity prior to any act of the intellect and accordingly that it has some sort of real distinction - the so called formal distinction - from the individual. On this score, he was attacked by William of Ockham, who, committed to a thorough nominalism, denied any sort of distinction within the individual that would grant the universal a reality of its own (see Nominalism; Universals). As such, Scotus and Ockham are typically viewed as poles in the fourteenth-century strain of the realist-nominalism debate. Scotus, however, was not an extreme realist. For instance, he argued at length against Henry of Ghent's theory which accorded the essences of things a real being in the mind of God antecedent to their creation (see Henry of Ghent). Even Ockham places Scotus next

to last in his series of opinions ranked according to their degree of realism.

Scotus does not directly treat the problem of the reality of universals, as one finds it treated in the commentaries of Boethius and Abelard, but rather addresses it in the course of determining the principle of individuation. By Scotus' time, the thirteenth-century discussion of individuation had become highly involved, leading Peter Olivi to remark that there was 'an endless forest of opinions on the matter'. Scotus reaches his own position after a lengthy examination and rejection of five possible views: a common opinion that there is no need to posit a separate principle of individuation, followed by four specific views: negation (Henry of Ghent), actual existence (a common view), quantity (Giles of Rome) and matter (a common view attributed to Aristotle). Scotus devotes a separate question to the elimination of each of these opinions, leaving him to conclude in a sixth view what the principle of individuation must be.

The greatest burden of Scotus' entire discussion is the refutation of the first view that there is no need to posit a distinct principle of individuation. The issue is whether a common nature, such as equinity or humanity, is of itself individual. This first view holds that the nature is individual of itself, so that there is no need to account for its individuality by any other factors than those that bring the nature itself into actual existence, namely, the generating causes themselves. It is not, in this view, that the nature is first produced as universal and then some intervening causes are required to contract it to a singular instance, for the nature is produced and exists only as singular. To the contrary, what is required is an explanation of the nature's universality, for this does not belong to the nature as it exists absolutely and in reality but only in relation to the intellect.

In essence, what Scotus is combating is the nominalistic position that reality is thoroughly singular and hence individuality requires no explanation. Scotus mounts two main arguments against this view, both of which bring out his realism. The first is that the object of a power, insofar as it functions as its object, is naturally prior to the act of that power. The reason is that a cause is prior to its effect, and the object is a cause of the act of a power. However, if the nature is of itself singular insofar as it is prior to an act of the intellect, then the intellect in its act of understanding will grasp its object in a way contrary to the very nature of that object itself, namely, as common rather than singular. Therefore, the nature cannot be of itself singular but must be the common antecedent to an act of the intellect.

Scotus' second argument issues in his doctrine of a lesser or 'minor' unity. He maintains that the nature must have its own proper unity which is both real and less than the numerical unity of the singular. Otherwise, every real unity would be numerical, which is false. The reason is that many relationships are recognized as real in the sense that they are not mind-dependent, yet are not based on things numerically one but on species, genera and other common classes. Therefore, these must have unity which is less than numerical but nonetheless real. For instance, the basis of all physical change, which is real, is contrariety; but things are not contrary insofar as they are numerically one, for then there would be as many contraries as individuals. Thus contraries - hot and cold, up and down - must each be one by a unity that is real but less than numerical. Or again, the relation of similarity is real in the sense that it is not simply the product of the mind. It cannot be based on what is numerically one, for then all things would be equally similar. Conversely, there are degrees of diversity that are not merely mind-imposed, so that Socrates differs more from rock than from Plato. This would not follow, however, if all unity were numerical, for then all individuals would be equally diverse.

Accordingly, Scotus concludes that the natures of things, such as equinity and humanity, are not of themselves individual but are the common antecedent to any act of the intellect. From this it follows that natures taken in themselves are not, strictly speaking, universal either, for universality in the strict sense is a relation of reason resulting from an act of the intellect. Quoting Avicenna's famous text on the common nature (*natura communis*), Scotus says that the nature taken in itself is neither universal nor singular: 'Equinity is nothing else but equinity alone. Of itself it is neither one nor many, neither universal nor particular' (*Ordinatio* 2 d.3 n.31) That is, according to Scotus, although the nature is never found except as universal in the mind or as singular outside the mind, it cannot of itself be either. If equinity were in itself universal, so as to include the note of universality in its definition, it could not be predicated of any singular instance, for no individual is a universal. If it were singular of itself, it could be asserted of only one instance. Thus, in order to be capable of realization in either state, the nature taken in itself must be neutral with respect to both. It is this common nature that forms the proper object of the intellect, functions as the predicate in true, universal statements, and has the real, lesser unity demonstrated above.

Given that the natures or essences of things are not of themselves singular, they must be made such by some individuating factor, just as they are made universal in the strict sense by an intervening act of the intellect. As indicated, Scotus rejects four candidates for this individuating principle. The first is Henry of Ghent's position that a nature is individual when it cannot be pluralized further (for example, Socrates cannot be multiplied) and is not identified with another (Socrates is not Plato).Thus, Henry concluded that a nature is individuated by a twofold negation. Scotus argues that an individual is something positive and thus cannot be caused by negation. In any event, Henry's theory does not give an exact cause, for every negation presupposes something positive. What is sought then is the positive factor that causes these two negative properties of an individual.

The next opinion is that actual existence individuates, which is based upon the principle that actuality distinguishes. Since existence is the ultimate act, it must cause the ultimate distinction, namely, individuality (see Henry of Ghent). Against this, Scotus argues that while existence is an act, it is not an act relevant to individuation. At issue is what makes some substance, such as a horse or stone, individual. Existence is an act outside of and posterior to the whole predicamental line of substance; it is in this sense that existence is often said to be 'accidental', for it lies outside the essence or natures of things. One of the more common views was that individuation was caused by quantity, since a form was taken to be pluralized insofar as it was found in an extended, material substrate. Scotus replies that if accidents are posterior to substance, this holds *a fortiori* of individual substance, since Aristotle identifies this as substance in the primary sense. Therefore, quantity as a accident is posterior to whatever makes a substance individual. Elsewhere, Scotus deploys this same line of reasoning against the Boethian theory that a collection of accidents individuates (see Boethius, A.M.S.). Finally, he rejects the standard Aristotelian view that matter individuates, since matter is in itself indeterminate and indistinct. It cannot therefore be a principle of distinction.

From all of this, Scotus concludes that the principle of individuation must be something real and positive in the substantial order as opposed to any kind of accident, whether existential or categorical, and, while not a substantial form itself, the ultimate reality or perfection of that form. In other words, the principle of individuation is a further substantial difference added to the specific nature; indeed, Scotus calls it an 'individual difference'. While the individual difference is of course not a further specific difference, Scotus depicts it as functioning metaphysically in a closely analogous way. Thus, just as the specific difference renders the nature of which is it a part incapable of division into any further species, so the individual difference renders the singular absolutely indivisible. Further, the specific difference is a reality formally distinct from, and actual with respect to, the reality of the genus. Also, the individual difference is actual with respect to the reality of the specific nature and formally distinct from it. Finally, the individual difference is irreducibly simple and hence wholly diverse from any other individual difference. In this it is comparable to ultimate specific differences, which are absolutely simple and diverse. The individual difference, however, is unlike any specific difference, because it adds no further quidditative or essential reality. If the nature or essence of a thing be considered its form, then the individuating difference may be considered 'material' in the extended sense that it contributes no common essence or nature but rather contracts such a nature to an ultimate subject. Posterity has labelled this individual difference *haecceitas* or 'thisness', a term used sparingly by Scotus himself and then usually to mean the state of being singular (*singularitas*) rather than the principle of individuation itself.

The significance of Scotus' theory of individuation is that it breaks with the fundamental Greek conception of the species as the principal locus of both being and intelligibility, codified in the Latin tradition by the Boethian dictum that 'The species is the entire being of an individual.' As schematized in the so called Porphyrian tree, differences proper in the category of substance were seen to end with the final species and individuation was explained through something extrinsic, whether by way of accidents or matter. Scotus, however, extends the process of division and differentiation in the substantial line past the species and down into the constitution of the individual itself, going so far as to place the species and individual difference in a relation of potency and act akin to that of genus and specific difference. He thus accords the individual a true reality and admits as a consequence that the individual is *per se* intelligible. In so elevating both the reality and intelligibility of the individual, Scotus' realism on the issue of universals is decidedly un-Platonic.

13 Intuitive and abstractive cognition

In the area of epistemology, Scotus' most influential contributions were the distinction between intuitive and

abstractive cognition and the demolition of Augustinian illumination, at least in the highly sophisticated form given to it by Henry of Ghent. While the latter is of broader philosophical interest, virtually every scholastic discussion in epistemology after Scotus utilizes his distinction between abstraction and intuition, which contemporaries claimed originated with him. Scotus' notion especially of intuitive cognition was, of course, subjected to refinement and revision in subsequent discussions, but always with Scotus' original definition in mind.

As defined technically by Scotus, intuitive cognition is knowledge of an object insofar as it is actually existing and present to the intellect. Abstractive cognition is knowledge of the object insofar as it is abstracted from actual existence or non-existence. A number of clarifications are in order. First of all, as will be clear from Scotus' argument for the distinction, both intuitive and abstractive cognition are acts of the intellect proper and do not differ in that intuition grasps the sense particular and abstraction the universal. Both types of cognition have as their object the essence or quiddity as opposed to the sense particular. In intuition, the quiddity is known as being caused by what is existing and present, in abstractive cognition by the intelligible species residing in the intellect as surrogate for the existing object itself. In this context, then, 'abstractive' does not for Scotus refer to Aristotelian abstraction of the universal. Second, Scotus is specific that 'intuitive' is not here equated with 'non-discursive', the common epistemological sense associated with the Augustinian term *intuitus* (glance), particularly in the context of divine knowledge or the beatific vision (see Augustinianism). Some abstractive knowledge can be 'intuitive' in this sense, since it can be non-discursive. Scotus says that he is here taking 'intuitive' absolutely, as when we say that we 'see (*intueri*) a thing as it really is'.

Scotus argues that the intellect must possess both types of cognition based upon its commonly admitted functions. Thus, the intellect must be capable of abstractive cognition, for otherwise scientific knowledge in the strict Aristotelian sense would be impossible. The reason is that an object is contingent insofar as it is actually existent and present to the intellect. If therefore the intellect cannot grasp an object in abstraction from its existence, all knowledge would be contingent. In other words, the intellect could know no statements about an object as true or false independent of that object's existential state. Conversely, the intellect must be capable of intuitive cognition, for a perfection found in a lower power must be found in a higher power of the same type. However, the senses, which are cognitive faculties like the intellect, seize the sensible particular as present and existing. Therefore, the intellect must also have this capacity. As Scotus explains, the particular senses have intuitive, sensible cognition of the particular, while the imagination knows the same object abstractively by means of the sensible species which can remain in the absence of the sensible thing itself. The same twofold cognitive capacity must, by parity, be found in the intellect. At the level of sense, however, two separate powers are required for these two different cognitive acts because the sense powers are distinguished by having different material organs. Owing to its greater perfection as an immaterial power, the intellect possesses both capacities in a united way. Furthermore, intuitive cognition is also required to account for the beatific vision, where the divine essence will be known, according to scripture, 'face to face'; that is, as existentially present to the intellect.

For Scotus, then, the intellect has a direct apprehension of an intelligible object insofar as it is the actually existing and present cause of its cognitive act. The chief philosophical use to which Scotus puts intuitive cognition is to supply certitude for contingent propositions. For example, he claims that by means of intuitive cognition we are as certain about our own acts as we are about necessary, self-evident propositions. After Scotus, the entire fourteenth-century preoccupation with certitude was regularly cast in terms of intuitive cognition. For instance, a common problem discussed was whether God could cause an intuitive cognition of a non-existent object (see William of Ockham §4).

14 Theory of will

While perhaps better known for his metaphysics than his ethics, Scotus' ethical theory has attracted increasing attention for being innovative and even radical. For example, he departs from fundamental thirteenth-century positions by holding that not all of the natural law (the decalogue) is absolutely binding, that prudence is not necessarily connected to moral virtue and that the will can act contrary to a fully correct moral judgment of the intellect. These and other such conclusions arise from Scotus' strong notion of will itself, which is complex and the focus of much of the attention given to his ethical theory. Three features of Scotus' conception of will have been seen as particularly important: the will as a power for opposites, the will as rational power and the dual

inclination or ‘affection’ (*affectio*) of the will.

Scotus holds that there is a twofold freedom arising from the will as a power for opposites. The will is free in an evident way, says Scotus, since it is capable of opposite acts successively, such as loving and hating. This type of freedom, however, is not a perfection, since it pertains to the will as changeable and variable. In a second, less evident way, Scotus argues, the will is also free apart from any succession or change, for at the very moment at which it is willing an act, it remains a real, active power to will the opposite. Obviously Scotus does not mean by this that the will is capable of willing contrary acts simultaneously. Rather, he means that, if there is to be a contingent and free cause called the will, an act must be consistent with the real possibility of its opposite at the same time. (Scotus goes to considerable lengths to clarify the logical ambiguities of his position.)

Scotus argues for this ‘less evident’ sense of freedom and contingency by means of his famous hypothetical case of an instantaneously existent will, which in fact derived from the standard scholastic question of whether an angel could have sinned at the first instant of its creation. Consider a created will that has been brought into existence only for an instant and at that instant has a determinate act of willing. Scotus argues that, despite existing only for an instant, this will cannot produce its volition necessarily, but must do so freely and contingently. The reason is that a cause, when it actually causes, must do so either necessarily or contingently. That is, a cause is not now contingent because it existed previously and then, at that previous time, was able either to cause or not, but only because it is such at the moment when it actually operates. Thus, if a will existing at an instant causes necessarily, it would cause in that way at every instant, and thus never be a free or contingent cause. Therefore, since the will causes contingently and freely at that instant, it must have a real power for the opposite at that same instant. The will is thus a power for opposites apart from any succession, for there is no succession at an instant.

In arguing that the will is a power for opposites apart from any succession or change, Scotus departed from a long standing conception of free choice, such as represented by the standard discussion of freedom in Lombard’s *Sentences*. There, Lombard states that choice is not free with respect to what is past or present, but only with respect to the future. The reason is that what is present is already determined, and it is not within our power to make what already is not be the case. Rather, we are only free to change what will be in the future. Scotus denies this on the above grounds that it would render the will a necessary rather than contingent and free cause, for the causal nature of the will is determined only when it operates as a cause. To be free, therefore, the will must be contingently related to its act of volition even at the moment of that act. This means that the will must have a real power for the opposite of what it wills at that very moment (see Free will).

The notion of contingency resulting from this particular aspect of Scotus’ doctrine of will is regarded by some as his most important philosophical contribution of all. In this connection, Scotus is regularly portrayed as breaking with Aristotelian conceptions of modality that persisted until the scholastic period. As the above account indicates, something is contingent according to Scotus if, at the moment it occurs, there is a real possibility for its opposite. This is in contrast to Aristotle’s construction of contingency, where something is contingent if its opposite can actually occur at some other time. In this, Scotus is seen as ushering in a modern conception of possibility previously thought to have begun with Leibniz. While Scotus’ originality on this score has been overstated - the basic doctrine of will behind this new notion of contingency is found in Peter Olivi - there can be little doubt that the extended analysis given to it by Scotus ensured its influence.

In a position related to the above conception of the will, Scotus maintained that the will was a rational power. Commenting on the text of Aristotle in which rational powers are defined as those capable of producing contrary effects, Scotus made the primary division of all active powers the natural versus the voluntary. A natural agent is one that is of itself determined to act. That is, a natural power will issue in a determinate act necessarily and to its greatest capacity unless impeded. A voluntary or free power is not determined of itself to act, so that it may issue in a contrary act or no act at all. By this Scotus really means that the will is self-determining. Its indeterminacy to act is not a defect owing to an insufficiency of power but a perfection that results from an abundance of power capable of contrary effects. Given this primary division of nature and will, Scotus places the intellect on the side of natural powers so that, in Aristotle’s definition, it is not strictly speaking rational. The will consequently became the only truly rational power, where ‘rational’ was contrasted with ‘naturally determined’. In a complete reversal of the intellectualist and Aristotelian model accepted by Aquinas, Scotus concluded that the intellect was rational only in the qualified sense that it is required as a precondition for the action of the will.

The will, however, is not only an active power, but an appetite with inclinations. Here too, Scotus sought to protect the will from natural determinism by adopting Anselm's distinction between an affection or inclination for the advantageous (*affectio commodi*) and an affection for justice (*affectio iustitiae*) (see Anselm of Canterbury §6). As interpreted by Scotus, the former is the inclination to self-fulfilment characteristic of natural desire. What is sought is the perfection of the agent. The latter is an inclination not for the good of the agent but for the good in itself. Scotus claims that the will has an 'innate' affection for the just and that this is the basis of its liberty. The affection for the just enables the will to transcend the determination of natural appetite to self-fulfilment by loving the supreme good, God, for its own sake or other lesser goods for their own worth (see Right and good §2).

List of works

Duns Scotus, John (*c.*1290-1308) *Opera omnia. Editio nova iuxta editionem Waddingi XII tomos continentem*, Paris: Vivès, 1891-5, 26 vols; selections ed. and trans. A.B. Wolter, *Duns Scotus on the Will and Morality*, Washington, DC: Catholic University, 1987; ed. and trans. A.B. Wolter and W.A. Frank, *Duns Scotus, Metaphysician*, Lafayette, IL: Purdue University Press, 1995.(The Vivès edition is a typographically enlarged reprint of the Wadding edition (Lyons, 1639). Contains many spurious works. For the certainly authentic works, see C. Balić (1966) *John Duns Scotus. Some Reflections on the Occasion of the Seventh Centenary of his Birth*, Rome: Scotistic Commission, 29-44. Since the critical Vatican edition is far from complete, this is still the only text for many of Scotus' writings. Even for those texts which have been critically edited, the edition remains valuable for the scholia, parallel citations and commentaries by later Scotists. Wolter (1987) contains extensive selections with facing Latin and substantial introductions; Wolter and Frank provide a re-translation of selected texts with commentary.)

Duns Scotus, John (*c.*1290-1308) *Opera omnia studio et cura Commissionis Scotisticae ad fidem codicum edita*, Vatican City: Typis Polyglottis Vaticanis, 1950-, 11 vols to date. (Planned critical or Vatican edition of Scotus' writings. Published to date are vols 1-7 (*Ordinatio* to bk 2, dist. 3), vols 16-19 (*Lectura*).)

Duns Scotus, John (before 1300) *Lectura*, in *Opera omnia studio et cura Commissionis Scotisticae ad fidem codicum edita*, Vatican City: Typis Polyglottis Vaticanis, 1950-, vols 16-19.(The questions on divine foreknowledge are translated by A. Vos, *Contingency and Freedom: John Duns Scotus, Lectura I 39*, Dordrecht: Kluwer, 1994.)

Duns Scotus, John (after 1300) *Ordinatio*, in *Opera omnia studio et cura Commissionis Scotisticae ad fidem codicum edita*, Vatican City: Typis Polyglottis Vaticanis, 1950-, vols 1-7.(The prologue is translated by A. Wolter in 'Duns Scotus on the Necessity of Revealed Knowledge', *Franciscan Studies* 11: 231-71, 1951. The question on whether God's existence is self-evident is translated in E. Fairweather, *A Scholastic Miscellany: Anselm to Ockham*, Philadelphia, PA: Westminster Press, 1956, 428-39. The questions on the principle of individuation are translated by P.V. Spade in *Five Texts on the Medieval Problem of Universals*, Indianapolis, IN: Hackett Publishing Company, 1994, 57-113. *Duns Scotus, Philosophical Writings*, trans. A. B. Wolter, Indianapolis, IN, and Cambridge: Hackett Publishing Company, 1987, is a translation of selections from the *Ordinatio* with facing Latin text of the Vivès edition.)

Duns Scotus, John (*c.*1302-5) *Reportatio parisiensis*, part trans. A. Wolter and M. Adams, 'Duns Scotus' Parisian Proof for the Existence of God', *Franciscan Studies* 42: 248-321, 1982.(Translation and edition of the Parisian verison of the proof for the existence of God.)

Duns Scotus, John (*c.*1306) *Quodlibetal Questions*, ed. F. Alluntis, *Obras del Doctor Sutil, Juan Duns Escoto: Cuestiones Cuodlibetales*, Madrid: Biblioteca De Autores Cristianos, 1968; trans. F. Alluntis and A.B. Wolter, *God and Creatures: The Quodlibetal Questions*, Princeton, NJ: Princeton University Press, 1975; repr. Washington, DC: Catholic University of America Press, 1987.(Alluntis' edition is a revision of Vivès text of the *Quodlibetal Questions*. Alluntis and Wolter's translation includes a helpful glossary of Scotistic vocabulary.)

Duns Scotus (*c.*1308) *De primo principio (On First Principle)*, ed. and trans. A.B. Wolter, *John Duns Scotus: A Treatise on God as First Principle*, Chicago, IL: Franciscan Herald Press, 1966; 2nd revised edn, 1983. (An edition and translation of *De primo principio*. The revised edition adds an extensive commentary.)

Duran, Profiat (d. *c*.1414)

Duran, known also as Efodi, produced a wide variety of works displaying a considerable understanding of Christian culture, which he then used to criticize Christianity from a Jewish perspective. Heavily influenced by both Maimonides and Abraham ibn Ezra, he stressed the dual nature of the Torah as a system of belief and practice. His work includes Neoplatonic and astrological ideas, and sought to emphasize the salvific force of the Torah.

Profiat Duran's given name was Isaac ben Moses Levi, but he is perhaps best known as Efodi. He was a Spanish-Jewish theologian and polemicist of the later fourteenth and early fifteenth centuries. An active anti-Christian polemicist, he was also the author of two philosophical works, the 'Introduction' to his grammatical work, *Ma'aseh Efod (The Making of the Ephod)* and a popular commentary to Maimonides's *Guide to the Perplexed*. In the former, Duran maintains that the Torah teaches true science (logic, physics, metaphysics) and is the best way to learn it. Such knowledge is important, but true felicity in this world and in the next depends upon proper fulfillment of the Torah's commandments (*mitzvot*). Duran deals with the different ways in which thinkers have analysed how the Torah is to be observed. Some had argued that all that is important is carrying out the *mitzvot*. It is not necessary to know why these commandments ought to be followed beyond recognizing that they are commandments, on the model of medical treatment where someone may not understand the workings of the treatment, yet undertake it and as a result be cured of the ailment. Duran disagrees with this view, arguing that the Torah has two parts, knowledge and practice. These parts are intimately connected, since it is necessary to have knowledge to understand how to carry out the commandments. Duran criticizes the view that religion and philosophy are in opposition to each other. Carrying out one's religious obligations, he argues, serves to attract the emanation of heaven, along the Neoplatonic pattern. Worship achieves the heights of perfection only in the Land of Israel, since it lies closer to the powerful forces of grace than anywhere else in the world. Nonetheless, the commandments must be obeyed wherever one is, and their fulfillment brings about happiness in this life.

Duran considers the claims of the Kabbalists and concludes that they are closer to the spirit of the Torah than are the philosophers, even more so if they are right in their claims to be able to affect the course of nature through their practices. Yet they also disagree among themselves a great deal, which is hardly an indication of a secure repository of truth. So, although philosophy and Kabbalah both have merits, the proper object of study is really the Torah, which is the only sure route to eternal happiness. In the Torah one is working with a holy language, and in studying it one participates in the holiness of the names which are to be found there. When the Temple existed, it was the conduit through which the divine emanation flowed to the people of Israel, and when it was destroyed (because the Jews had stopped studying Scripture) it was replaced by the Torah. The Torah is the only path to the highest happiness, and the only route to God is through carrying out its commandments. Theoretical knowledge in itself is incapable of attaining this eternal and complete happiness, and only the Jews are really able to carry out the proper role of human beings in serving God through carrying out his commandments. The Torah represents the source of divine providence for the Jews and guarantees their survival, despite the many dangers and disasters which they undergo. Duran was no doubt reflecting from his own experience here, for he had been forced to convert to Christianity and was able to practice openly as a Jew only later in his life. Although he defended stoutly the study of the Torah, he also accepted the importance of the natural sciences so long as they do not contradict the foundations of the faith.

Duran's *Commentary on the 'Guide to the Perplexed'* is printed in the standard editions of that work. It is brief, literal and very conservative, trying to present Maimonides as a thinker well within the mainstream of received Judaism. In places where Maimonides seems to interpret Judaism in too thoroughly Aristotelian a manner, Duran sands down the rough edges, pulling Maimonides back in the direction of traditionalist orthodoxy. On the other hand, he frankly acknowledges the dangers of some of Maimonides's arguments as far as religion is concerned. His conservatism is in many ways typical of the Jewish philosophers of the late fourteenth and early fifteenth centuries. He did, after all, have to respond both to the continual spiritual crises in the Spanish Jewish community as a result of the conversionary pressures of the Christians, and to the impact of the Jewish Averroist movement (see Averroism, Jewish). On the other hand, his arguments for the role of the Torah in reconciling the physical and spiritual aspects of humanity was to play a large role in Jewish philosophy in the fifteenth century on its approach

to modernity.

Duran, Simeon ben Tzemach (1361-1444)

Simeon Duran was chiefly a religious thinker who incorporated a variety of philosophical traditions into his thought. He argues that revelation is the only certain route to knowledge. Following this principle, he criticizes those who argued that some of the principles of religion are more important or basic than others. To reject any aspect of religious law is to abandon the whole, and on this point Duran sets himself against Maimonides.

1 Life and works

Simeon ben Zemah Duran, Spanish *halakhist* and theologian, fled the anti-Jewish outbreaks of 1391 and spent the rest of his life in North Africa. Duran is best known as the author of numerous *responsa* (written answers to *halakhic* inquiries), from which much can be learned concerning the history of the Jews of Spain and North Africa in general and in particular of conversos (Jews forcibly converted to Christianity). He is also the author of a number of theological and polemical works that reflect a moderate Maimonideanism: Duran accepts the basic naturalism of Maimonides's Aristotelian view of the world while moderating its intellectualism. Duran's polemic against Christianity and Islam (*Keshet u-Magen*) is not philosophical in character. His most important contribution to Jewish thought is in the area of dogmatics, found primarily in two commentaries, *Ohev Mishpat (Lover of Justice)* - a work on Job and *Magen Avot (Shield of the Fathers)* - a work on Tractate Avot. The introduction to the former includes an extensive discussion of divine providence.

2 Dogma and the nature of Judaism

The issue of dogma had been introduced into medieval Judaism by Moses Maimonides (1138-1204), who formulated thirteen articles of belief in his commentary on the Mishnaic tractate Sanhedrin. Maimonides's enormously influential account of these doctrines of Judaism was presented, in effect, as an answer to the question: who is a Jew? In his discussions, Duran approaches the issue from a number of perspectives, not one of them that of Maimonides. In one place, Duran asks a structural question: construing Judaism as a deductive science, what are its axioms? His answer is: creation and providence. Providence, however, can be derived from creation, so in fact creation is the only basic principle of Judaism. In a second place, Duran seeks to explicate and defend Maimonides's account of the Jewish creed, reducing his thirteen dogmas to three: God's existence, Torah from heaven (that is, divine revelation as manifested in the giving of the Torah), and divine retribution. This account seems to have decisively influenced Joseph Albo (fifteenth century) in his *Sefer ha-'Iqqarim (Book of Principles)*. This second account, however, is not merely a summary of Maimonides, since it depends upon and even derives from Duran's third discussion, which diverges crucially from Maimonides. In this discussion Duran makes the claim that Judaism has only one principle - to believe what the Torah teaches - or, alternatively, that Judaism has as many principles as there are commandments in the Torah. It is in the context of this discussion that Duran defines heresy, not as false belief, but as the conscious rejection of a belief known to be taught by the Torah or the conscious adoption of a belief known to be denied by the Torah. The relative liberalism represented by Duran's departure from the idea of a fixed set of dogmas constitutive of Jewish faith is extremely rare in medieval religion.

Duran's three accounts answer three different questions:

(1) Construing Judaism as a deductive science, what are its axioms?
(2) Why did Maimonides posit the beliefs he did in his 'Thirteen Principles'?
(3) What is heresy?

Many of Duran's ideas were new and unprecedented but his influence was modest at best, both because his views were not adequately understood in his own day and because he wrote near the end of the period of active medieval Jewish philosphical discussion.

Durandus of St Pourçain (1275?-1334)

Although strongly Aristotelian in outlook, Durandus rejected certain classic points of Thomist doctrine such as the speculative 'scientific' and unique nature of theology, the theory of the active intellect and the doctrine of species. After carrying out a detailed examination of the Thomist theses, Durandus decided firmly in favour of theology being faith in revelation, something aenigmatica *and therefore meritorious. In this way, in the opinion of some modern scholars, he anticipated the position of William of Ockham; the position later known as 'Ockham's razor' appears more than once in his writings.*

The date of Durandus' birth is uncertain, but is believed to be about 1275. Early references speak of his presence in the convent of St Jacques in Paris, where he obtained a *licentia docendi* in 1312, and of the fact that as early as 1306 he had been criticized by a brother Dominican, Hervaeus Natalis, for an assertion contained in his *Commentariorum* (commentary on the *Sentences* of Peter Lombard), a work that was probably unfinished at the time but was no doubt already in circulation among the 'curious', as Durandus himself complained. In 1313, Pope Clement V made Durandus lector of the Holy Palace, and four years later, Pope John XXII made him bishop of Limoux, thus freeing him from his vow of obedience to the Dominican Order. In 1318 he became bishop of Le Puy and, in 1326, bishop of Meaux. He died in Meaux in 1334.

Following further criticism of his *Commentariorum* in 1314 and 1316, the Dominican Order carried out two formal inquiries, which concluded that certain theses contained in the work were dangerous and likely to impair that unity of doctrine which legitimized the intellectual independence of the Dominicans. At this time the teaching of the doctrines of Aquinas was becoming increasingly dominant; Thomist doctrine was defended repeatedly as being 'the soundest', while anyone who 'acted in a contrary manner and in spite of warnings failed to withdraw from his position' was severely censured. The disagreement between Durandus and his order continued, and the second edition of his commentary on the *Sentences* appeared in a reduced and expurgated form in 1310-11. In a later third edition (1317?-27), the censured points were to some extent restored.

In addition to three editions of his commentary on the *Sentences*, Durandus' works include the *Quodlibeta*, the *Quaestiones de habitibus (Questions About States)*, *De libero arbitrio (On Free Will)* and *De natura cognitionis (On the Nature of Cognition)*, written in Paris, three further *Quodlibeta* written in Avignon, and the *De origine jurisdictionum (The Origins of Jurisdictions)*, written while he was bishop of Meaux. In 1333, after being consulted by the pope and asked to express his opinion on the theory of the beatific vision, Durandus wrote *De visione Dei (The Vision of God)*, but this failed to win the approval of John XXII, who submitted it to a committee of censors.

The originality of Durandus as a theologian lies in the fact that he remained fundamentally faithful to Aristotelian-Thomist subjects and terminology, while diverging from that tradition in his conclusions. At the same time, he appears to have stood outside the anti-Thomist Augustinian tradition of the Franciscans (see Augustinianism). The chief problem for the historian is how to interpret the accusations of 'aversion to Thomism' which his contemporaries launched against him and which were later repeated in sixteenth century editions of the *Commentariorum* (Lyon 1558, Venice 1589). There is a theoretical consistency in Durandus' opposition to Aquinas, which emerges particularly over the question of the scientific nature of theology discussed in the commentary, showing that Durandus possessed his own clear-cut epistemology. Articles of faith, which Aquinas likened to the principles of knowledge, in Durandus' view are not 'rational', nor can they be referred to other self-evident principles, but 'only believed'. Faith is unconnected both with knowledge based on reasoning and with that obtained by way of experience. The subject of theology is supernatural and therefore not to be examined by man with his natural cognitive faculty; and it follows that the theological process itself cannot be rational. ' It is unreal to postulate a supernatural light that does not exist in all men and cannot be given to those who do not possess it' (*Commentariorum* 1, f.5 v.17).

Such statements are linked with fundamental points of Durandus' metaphysics and epistemology. The intellectual act itself is able to apprehend reality without the mediation of images (the 'species' of the Thomists), and *in se* can perceive individuals. Universals do not exist since everything that exists is individual. The formal distinction drawn by Duns Scotus between real beings and conceptual beings is 'frivolous' and leads to the conclusion that

man's knowledge of God is purely nominal. Truth may be defined as the formal condition of the object of knowledge, the relation between being and being perceived. It may be added that more than once in the course of discussion Durandus appealed to what was later to be known as Ockham's razor by asserting that *frustra ponuntur plura ubi pauciora sufficiunt* (it is futile to do with more what can be done with fewer) (see William of Ockham).

Durandus' principal thesis is that the theology of a human being who is a *viator* (one who has not yet attained the beatific vision) is based on belief in Scripture, which speaks in the language of metaphor capable of imparting not knowledge but moral teaching. Theology, Durandus remarks, is like rules of navigation which must be observed by sailors if they are to voyage in safety even 'if the stars are not of interest to them in themselves'. If the theologian exceeds these limits and launches into demonstrations that are no more than apparent, 'he assumes the capacity of the philosopher and loses his definition of theologian'. For Durandus, theology was an enigmatic body of knowledge and therefore meritorious for men, since ' it is not true that theologians or simple believers know the will of God and from this draw further knowledge' (*Commentariorum* f.11 r.10).

Durkheim, Émile (1858-1917)

Émile Durkheim is generally recognized to be one of the founders of sociology as a distinct scientific discipline. Trained as a philosopher, Durkheim identified the central theme of sociology as the emergence and persistence of morality and social solidarity (along with their pathologies) in modern and traditional human societies. His distinctive approach to sociology was to adopt the positivistic method in identifying and explaining social facts - the facts of the moral life. Sociology was to be, in Durkheim's own words, a science of ethics.

Durkheim's sociology combined a positivistic methodology of research with an idealistic theory of social solidarity. On the one hand, Durkheim forcefully claimed that the empirical observation and analysis of regularities in the social world must be the starting point of the sociological enterprise; on the other hand, he was equally emphatic in claiming that sociological investigation must deal with the ultimate ends of human action - the moral values and goals that guide human conduct and create the essential conditions for social solidarity. Accordingly, in his scholarly writings on the division of labour, on suicide, on education, and on religion, Durkheim sought to identify through empirical evidence the major sources of social solidarity and of the social pathologies that undermine it.

1 Intellectual biography

Émile Durkheim was born in Epinal (France) in 1858 to a three-generation family of Jewish rabbis. From an early age he was being trained to become a rabbi, but in his youth he first had a passing religious crisis, and later broke away from Judaism and became agnostic. Durkheim was trained in philosophy at the École Normale Supérieure in Paris, influenced by such thinkers as Charles Renouvier and Émile Boutroux, and obtained his *agregation de philosophie* in 1882. He taught philosophy at various Parisian *lycées* early in his career. In 1887 he first taught and later became professor of social sciences at the University of Bordeaux, a position he held until 1902 when he became first professor of education and later professor of education and sociology at the prestigious Sorbonne in Paris until the year of his death.

During his tenure at the University of Bordeaux, Durkheim published in quick succession three major works that qualified him as one of sociology's founders: *The Division of Labor in Society* (1893), *The Rules of Sociological Method* (1895), and *Suicide: A Study in Sociology* (1897). During that same period Durkheim established the *Année sociologique,* France's first sociology journal, and directed a social science research group that gravitated around the journal. Durkheim's years at the Sorbonne were characterized by a focus on the broad philosophical and ethical themes he recognized to be at the centre of the sociological enterprise. He lectured extensively on his philosophy of human nature, on value judgments in the social sciences, on epistemology, on the history of pedagogy, on moral education, and on religion. His last major monograph, *The Elementary Forms of the Religious Life* was published in 1912. Greatly saddened by the loss of his own son and close friends during the First World War, Émile Durkheim died in 1917, aged 59.

2 The sociological method

In his attempt to establish sociology as an academic discipline, Durkheim sought to identify early in his work the distinctiveness of the sociological approach and its unique methodology of sociological research. First, Durkheim established that society was not simply equivalent to the sum of its individual members; using a chemical metaphor, he viewed it as an organic compound endowed with qualities that surpassed the qualities of its constituting elements. While advocating that sociology should follow the path of the natural sciences and life sciences in developing a scientific standing, Durkheim realized that social facts - the phenomena of the moral life - were very different from the phenomena observed in the natural world. Social facts were representations of the collective life of society: laws, religious beliefs, norms, myths, customs. But the sociologist should treat them with the same empirical scrutiny natural scientists afforded to the phenomena of nature. According to Durkheim, we must treat social facts as things, and to identify social facts we must rely on the two characteristics they display: they are external to individuals and they constrain them. Social facts are obligatory, and their transgressions are punished with appropriate social sanctions.

Social facts are independent of individuals, and as such they are not affected by individuals' behaviour. The causes

of social facts, instead, must be sought in antecedent social facts; for instance, the social fact of punishment is causally explained by the strong collective sentiments felt by a society against a particular kind of behaviour. At the same time, social facts also perform a function in society - they are the means for the achievement of societal ends. The social fact of punishment, for instance, seeks to maintain and reinforce the collective sentiments that sanction the improper conduct of society's members. Durkheim acknowledged the importance of investigating both the causes and the functions of social facts, but he emphasized that functional analysis is distinctively sociological in that it seeks to relate a social fact to the larger social organism.

Following through his metaphor of society as an organism, Durkheim classified social facts as normal or pathological, in terms of their relation with the larger social environment - with the social organism as a whole. The adequacy of a social fact like a social norm must be evaluated in terms of the social ends such a norm fosters - this requires that the sociologist evaluate the desirability of social ends. Durkheim argued that value judgments are inevitable in the social sciences, since the facts of society are the values and beliefs of the collectivity (see Value judgments in social science §1). Thus, a scientific sociology must be able to identify desirable social goals before it can identify the best means to achieve them. Here, I believe, Durkheim's positivistic methodology and idealistic social theory show their greatest strain as he tries to make value judgments amenable to direct scientific investigation (see Positivism in the social sciences). Such strain is reflected in Durkheim's substantive sociological research on the division of labour and on suicide.

3 Social solidarity and social pathologies

Durkheim's empirical research on the division of labour and on suicide demonstrated the potential of sociology as an academic discipline by taking up topics that had been previously analysed by other social sciences, and showing that sociology's distinctive approach shed a new light on them.

The division of labour was considered an economic phenomenon that led to increased production and wealth. Durkheim argued that the division of labour was also an important moral phenomenon that described the changing foundations of social solidarity from traditional to modern societies. On the one hand, traditional societies exhibited relatively undifferentiated roles of individuals in economic life; individuals were able to perform a variety of tasks and were basically interchangeable with each other. Social solidarity in traditional societies emerged from the unmediated identity of its members. Durkheim called this traditional form of social solidarity mechanical solidarity. On the other hand, modern societies are characterized by a high degree of differentiation of tasks in economic life, and individuals are highly interdependent in their economic activities. Social solidarity in modern societies emerges from the functional interdependence of individuals' differentiated roles; this modern form of social solidarity he calls organic solidarity. Thus, the increase in the division of labour was not detrimental in modern societies, but rather provided a new organic source of solidarity to replace the waning mechanical solidarity of traditional societies. But Durkheim was also concerned with the social pathologies manifested in highly differentiated societies; specifically, he identified a condition of 'anomic' division of labour whereby the norms that bind the economic activities of individuals are greatly weakened. The anomic division of labour led to a loss of social solidarity, and society as a whole suffered from it. Guided by his idealistic standard of social solidarity, Durkheim failed to consider the possibility that the weakening of social norms was in fact a normal and inevitable feature of modernity.

Suicide was another topic Durkheim claimed as rightfully sociological. While psychological, biological, and ecological explanations had been provided, Durkheim argued that suicide was also a significant social phenomenon to be explained sociologically. Suicide rates illustrated how insufficient or excessive regulation and integration in the social organism led to a predictable quota of voluntary deaths, year after year. Durkheim was particularly concerned with the social pathologies of modernity, as he identified two pertinent types of suicide: egoistic suicide and anomic suicide. Egoistic suicide was prompted by the insufficient integration and attachment of individuals to society, demonstrated by the higher rates of suicide observed in Protestant countries as compared to Catholic countries. Anomic suicide was prompted by society's weakened regulation of individuals' conduct, especially in economic life, as demonstrated by the higher rates of suicide found in industrial societies as compared to agricultural societies. Egoistic and anomic suicide shared the spotlight in Durkheim's study because they both illustrated his concern with the underlying pathology of modernity: the loosening of individuals' attachment to society and the breakdown of the social norms that should restrain individuals' asocial behaviour. As

with his theory of the anomic division of labour, Durkheim's theory of egoistic and anomic suicide failed to consider suicide as, possibly, a normal phenomenon of our times, deriving from the collectivity's value of the freedom and autonomy of individuals as the cornerstone of modernity.

4 Moral education and religion

In the last two decades of his life Durkheim turned his attention away from the pathologies of modernity, to focus on the central role of education and religion in creating, renewing, and sustaining social solidarity.

In his lectures on moral education (published posthumously in 1925) Durkheim argued that education should provide individuals with discipline, attachment to society, and autonomy of judgment. The first element guaranteed society's successful role in regulating the conduct of its members; the second gave individuals a sense of belonging and of successful integration with the collectivity; the third equipped the competent member of society with the ability autonomously to discern the desirability of society's moral values and to subscribe to them spontaneously. The themes of insufficient regulation and social integration that characterized Durkheim's work on suicide were recast here in a positive form: how to achieve successful regulation and social integration in modern societies. The theme of autonomy, then, echoed Durkheim's repeated emphasis that the dignity of the individual was unquestionably the central moral value of modernity.

Durkheim's work on religion brought to full circle his characterization of society as centred on collective representations. Criticizing the Marxist approach, Durkheim rejected the view that economic life preceded religious phenomena; instead he argued that in primitive societies everything was religious. In *The Elementary Forms of the Religious Life* Durkheim demonstrated the centrality of religion in providing the cognitive, intellectual and moral foundations of social life. He argued that since religious phenomena were the earliest expression of social life they were also the source of our rules of logic and of our system of thought. The categories of time and space, of class and number, and of genus and species must have originated in the early experience of the collectivity, manifested through religious life. Thus, for example, the idea of time and of its division of years and seasons emerged, in Durkheim's view, from the religious distribution of ceremonies, rituals and holidays in primitive societies.

By demonstrating that cognitive and moral phenomena found their roots in primitive religious life Durkheim sought to prove that everything is social in its origins. This was, in the end, Durkheim's master thesis, that society is the source of everything that makes us human - moral rules, altruism, rules of logic, cognitive categories, and ultimate beliefs and values. Accordingly, he constantly downplayed the role of psychology, of economics, of history, and constantly emphasized the role of collective representations in shaping the life of society and of its members. Perhaps Durkheim's philosophy was exceedingly sociocentric; it was certainly unambiguous and forceful in making the case for sociology as the science of moral life.

Duty

To have a duty is, above all, to be subject to a binding, normative requirement. This means that unless there are exculpating reasons someone who has a duty is required to satisfy it, and can be justifiably criticized for not doing so. Having a duty to do something is like having been given a command by someone who has a right to be obeyed: it must be done.

Sometimes we speak as if we have duties to individuals (such as persons and institutions). So, for example, if Jones makes a promise to Smith, then Jones has a duty to Smith to keep the promise. We also talk as if we have duties to perform, or to refrain from performing, types of actions, for instance, a duty to help those in need. Even if the performance of such a duty involves treating an individual in a certain way, the duty may not be to that individual. For example, a duty to be charitable might not be a duty to anyone, not even the recipient of the charity.

An important feature of duties is that they provide some justifying reason for action. If we explain why we did something by saying that it was our duty, we are offering a justification for the action. Such a justifying reason does not depend on the entire nature of the action. For example, if we make a promise, we have some justifying reason for keeping it, regardless of what was promised, or to whom the promise was made. Again it is like a command. If we are given a command by someone with a right to be obeyed, we have some justification for obeying it, no matter what we are commanded to do. On some views, however, the justifying reason we have for doing something because it is required by duty may not be decisive: we may have an even better reason for doing something else. None the less, that something is required by duty provides some justifying reason for doing it.

Talk about duties is found in many areas; we speak, for example, of legal duties, moral duties, professional duties, the duties of a scholar and, even, matrimonial duties. This discussion will focus on moral duty, but may have wider application.

1 Duty and other normative concepts

Related to the concept of duty are a number of other important normative concepts. Among these are the concepts of obligation, right, permission and prohibition. The relations between permissions, prohibitions and duties are fairly straightforward: if we are permitted to do something, then we do not have a duty not to do it; if we are prohibited from doing something, we have a duty not to do it (see Deontic logic). The relationships between duties, obligations and rights are not as obvious.

According to most modern use, obligation and duty are taken to be coextensive, if not identical. So, to have a duty to do something is the same as to have an obligation to do it. However, there is a narrower view concerning duty. According to this, duties must result from roles, namely, from status, occupation or position. For example, subjects are said to have duties to their sovereign, physicians to their patients and parents to their children. The duty arises from the role (being a subject, physician or parent). Obligations are distinct from duties on this view. Obligations result only from voluntary actions; for instance, an obligation might result from the making of a promise. It may be that the distinction between duties and obligations is currently seldom recognized because many of our roles are taken on voluntarily. Although there is much to be said for the narrower view, for the rest of this essay current usage will be followed and it will be assumed that duties and obligations are substantially the same.

One important view about the relationship between rights and duties is that there is a correlation between, at least, some rights and duties. A version of this thesis is expressed in the two following principles Ross (1930: 48).

1 A right of *A* against *B* implies a duty of *B* to *A*.
2 A duty of *B* to *A* implies a right of *A* against *B*.

It should be noted that accepting these principles does not force us to accept the less plausible view that there is a general correlation between rights and duties, such that every right implies a duty and every duty implies a right. As has been pointed out, there may be duties concerning individuals which are not duties to those individuals. Likewise, individuals may have rights which are not rights against anyone in particular. About such cases the above principles are silent. Rather, the proposal is that there is a correlation between, for example, Smith’s having a duty to Jones, and Jones’ having a right against Smith (see Rights).

An evaluation of these principles requires that we examine the following questions. (1) What can have duties? (2) To what can there be duties? (3) What can have rights? (4) Against what can there be rights?

The answers to (1) and (4) are fairly clear. It is reasonable to think that in order for an entity to have a duty, or for there to be a right against it, that entity must be able to recognize that it is subject to a normative requirement, a cognitive ability lacked by beings that are not rational (see Moral agents). Consequently, only persons (rational beings), such as humans, can have duties and we can have rights only against persons. This still leaves open whether non-persons can have rights and whether we can have duties to non-persons. Can we, for example, have duties to nonhuman animals, or, perhaps, the biosphere? Can such things have rights against us? (See Animals and ethics; Environmental ethics.)

One important view is that non-rational beings cannot have rights and we cannot have duties to them. Again, the thought is that a required cognitive capacity is lacking. It is sometimes argued that having any right, let alone a right against someone, requires the ability to claim it. Even according to this view, however, we might have duties concerning non-persons, or with respect to them. We could, for example, have a duty not to cause non-persons unnecessary pain, without its being a duty to anyone. Accepting this view would not require rejection of either of the principles.

An alternative view argues that for an individual to have a right, or for us to have a duty to that individual, does not require that individual to have anything like the cognitive capacity needed to have a duty, or to be the sort of thing against whom others can have rights. The standards are different. Perhaps all that is needed is being sentient, or having interests. If so, then we could accept that some non-persons can have rights against us and that we can have duties to some non-persons. This also is consistent with both of the principles.

One possible reason for rejecting the principle that a duty of *B* to *A* implies a right of *A* against *B* is the thought that we can have duties to ourselves, but cannot have rights against ourselves. The idea that persons can have rights against themselves is difficult to accept. That persons can have duties to themselves, such as that of self-improvement, seems much more plausible. However, if we take it that a duty to a person involves what is owed to that person, then the idea is much less plausible: can we really owe anything to ourselves? Alternatively, it might be that we have duties that concern ourselves, without their actually being duties to ourselves. If this is so, then no reason has been offered for rejecting the two principles (see Moral standing).

2 Kinds of duties

A number of distinctions have been offered between types or kinds of duties. The most important of these distinctions are those between positive and negative duties, *prima facie* and ‘all-in’ duties or ‘all things considered’ duties, perfect and imperfect duties, and subjective and objective duties.

The distinction between positive and negative duties is supposed to rest on a more fundamental difference between acting and refraining from acting. The idea is that positive duties concern what we are required to do, while negative duties concern what we are required to refrain from doing. Examples of positive duties might be the duties to help others and to develop our talents. Examples of negative duties might be the duties not to lie and not to kill.
